- 1 *Representative of Association of Association of Honorary Staffs of the Major (Non Undergraduate Teaching) Voluntary Hospitals of England and Wales*  
 Mr H J McCurrah, Hove

## INDUCEMENT PAYMENTS

A sum equal to 1% of the central pool which is being established for the payment of general medical practitioners is being set aside to provide inducement payments to assist doctors to practise in peculiarly difficult areas—e.g., those which are sparsely populated or unpopular. The Ministry of Health, after discussions with the Negotiating Committee, has recently told executive councils how to proceed in this matter. They should consider, in consultation with the local medical committee, any cases where they are satisfied that general medical services adequate to the needs of the district cannot be provided or maintained without an inducement payment. Among the grounds for recommending such payments might be (1) Vacancy advertised, but no applications received (2) Vacancy to be advertised for an area which has in the past always attracted too few doctors (3) An existing doctor unable to remain for the income which he might expect to receive without an inducement payment (4) An existing doctor who previously received special assistance under the NHI Scheme, the loss of which will cause undue hardship (5) An existing doctor with an abnormal number of aged and chronic sick on his list, or a vacancy in an area with an abnormal number of such persons.

It is not intended that inducement payments should be made in cases where the difficulty can be met by a basic salary of £300 per annum. The Minister will refer proposals put up by executive councils to the Medical Practices Committee, and all payments approved by the Minister must be reviewed annually by the executive council in consultation with the local medical committee.

## National Health Service News

## Prescription of Appliances

Executive councils have recently been requested by the Ministry of Health to inform all the chemists in their areas that only those appliances listed in the Third Schedule to the National Health Service (General Medical and Pharmaceutical Services) Regulations, 1948, may properly be prescribed on Form EC 10 by medical practitioners, and may be dispensed by chemists. Specifications of appliances additional to those supplied under the National Health Insurance (Medical Benefit) Regulations, 1936, are to be issued shortly. Chemists should meet prescriptions for appliances in general and especially for elastic surgical hosiery and trusses, by supplying standard grades and qualities, except where the prescriber has specified a particular grade or quality.

## Foreign Visitors and NHS

Visitors staying in Britain for less than two months are entitled to treatment under the National Health Service as temporary residents. They should not be included in a doctor's permanent list unless they remain for three months or more, in which case they should state their national registration identity number.

## PRESCRIBING ON EC 10

The Ministry of Health has issued the following statement about the use of the official prescription form.

There is considerable misunderstanding among doctors as to the use of the official prescription form, EC 10. This may be used only

1 By doctors who have agreed to give general medical services under Part IV of the National Health Service Act

2 For named patients on their lists or patients accepted by them for treatment as temporary residents. A separate form must be used for each member of the family

3 For ordering drugs and medicines or the prescribed appliances and reagents named in the Third Schedule to the National Health Service (General Medical and Pharmaceutical Services) Regulations, 1948

EC 10 may not be used

- 1 For ordering medicines, etc., for private patients
- 2 For ordering foods and food like preparations
- 3 For ordering appliances not in the prescribed list
- 4 For obtaining stocks of drugs or appliances required by the doctor in his practice. These he should obtain from his wholesaler or a local chemist in the usual manner

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton le Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley

The Home Office announces that Dr William Henry Armistead, of Paisley, is no longer authorized under the Dangerous Drugs Act to be in possession of or to supply dangerous drugs.

## Correspondence

### Obstetric Committees

SIR—Something is radically wrong and impracticable in the present attempt to improve the midwifery service by dividing doctors into those who are on the 'Special List' and those who are not. The former are to be first on call for midwives' cases and to receive 7 guineas for cases they personally conduct from start to finish. The latter are to be second on call and are to receive 5 guineas for cases personally conducted.

It is to be deprecated if, as seems likely, the names of those on the special list are published in post offices alongside the general list. The general public will naturally feel that those with the hall mark of the local executive council are the better doctors. I am sure that this method of trying to improve midwifery will in the long run prove a miserable failure.

The teaching and practical experience given students is sufficient to give them a reasonable working knowledge. As a practising obstetrician I know that just as in operating it is only by constant contact and practical experience that one maintains efficiency. What a discouragement it must be to a recently qualified and keen doctor to know that he has not been appointed to the special list. How can he ever qualify for it? It is well known that only a small proportion of those qualifying can hold a resident post in a maternity hospital, while most postgraduate courses are non-resident and consist mainly of some lectures and demonstrations.

The vast majority of calls to midwives' cases are for such minor things as lacerations, but answering the call gives the young doctor confidence and experience. In major problems he has an expert specialist to call on, and he can send his patient into hospital by ambulance.

Durham Obstetric Committee were recently faced with a list of some hundreds of doctors from different areas in the county, most of whom were personally unknown to the members of the committee. How on earth could any discrimination be made? They were appointed on the special list *en bloc* because they had expressed a wish to practise obstetrics. This was the only logical course at the present stage of the evolution of midwifery. Similar action had already been taken by Northumberland County, Newcastle, Gateshead, and Tynemouth—I am, etc.

Newcastle-upon Tyne

FARQUHAR MURRAY

### Remuneration of Specialists

SIR—Under the Supplementary Ophthalmic Services Regulations the technical skill of an optician in dispensing a prescription for spectacles is valued at £1 5s a pair, the medical eye specialist who prescribes them is paid one and a half guineas per case in some recognition of his longer training and greater responsibility. At the lowest estimate, the most junior medical eye specialist can examine six patients comfortably in a half-day session of three hours, and in ten such sessions each week at regular times over forty-six weeks in the year (which should be easily achieved) he can earn £4,347.

The Minister having established this economic basis for discussion cannot honourably evade a contention that the labours and responsibilities of physicians, surgeons, anaesthetists, radiologists and others deserve no less favourable reward (nor can he doubt that opticians will resent with vigorous action any breach of faith entailing reduction of their agreed rate of remuneration which serves as a starting point of this argument).

In negotiations regarding the value of the contributions to the health and life of patients by consultants and specialists in any branch of medicine or surgery and of the continued study, professional skill and working hours entailed these facts should be borne in mind. It is immediately apparent how inadequate a reward for any member of the senior staff of a hospital is the suggested interim figure of £2,000 a year for the equivalent of ten three hour sessions a week (if so many can be achieved) of which a proportion may be spent in the physically and mentally exhausting conditions of an operating theatre some after a trying journey and others at unspecified hours—I am, etc.

Hull

D D STENHOUSE STEWART

### War Service of Specialists

SIR—Dr C A Hinds Howell's letter (Aug 21, p 90) raises a question that must have disquieted many ex-Servicemen but which does not appear to have attracted much attention. In common with others, specialists both gained and lost by war service. The gains were mostly intangible though not unimportant, but the losses were very material. They resulted mainly from the fact that those in the Forces were usually denied those opportunities for gaining experience, qualifications, position, and wealth that were often the lot of those who remained behind. Ex-Servicemen accepted these misfortunes of war in good part, hoping to remedy the position as the years went by and, perhaps, secretly believing that the spiritual gains of the war may prove a long-term investment.

There now arises the danger that the NHS Act may make these disadvantages permanent. It would indeed be unjust to ex-Servicemen if the very Government that they served should now consolidate the gains of those who served in less detrimental ways or who did not serve at all.

Paragraph 11 of the Spens Report advises that authorities be empowered to allow four special increments of £125 in respect to age, experience, and qualifications to those who first attain an appointment some years after the age of 32. I suggest that ex-Servicemen could be partly compensated for the above-mentioned losses by recognizing these increments as an entitlement in respect to war service—I am, etc.

Hull

J CLAPHAM COATES

### Doctors' Employees

SIR—May I draw your attention to the position of doctors' employees, especially those required in a busy practice of at least three doctors? Executive councils are at liberty to appoint shorthand typists and clerks at Civil Service rates of pay, who also work overtime as required, and I am sure these people do not work overtime for the mere love of the work. In addition to these employees there are also office cleaners, who I hardly imagine are paid out of the clerk's salary.

Few people may realize the amount and variety of work required behind the scenes in a busy practice, which is done while doctors are visiting patients. During surgery hours, three times a day, there might be two doctors consulting at the same time, using two consulting-rooms, instruments, and two waiting-rooms. There are bells to answer from two doors, cards to have ready for each patient, and a telephone to answer. There is full-time work for two people, with overtime every evening to 6.30 p.m. during the summer time and for nine months of the year until 7.30–8.30 p.m.

The new Education Act provides for secretaries to all types of schools, and under the old system nearly all secondary schools had one secretary. From experience in educational and medical work I can safely say there is as much general secretarial work necessary in a practice of three doctors as in a London grammar or county school, not forgetting the cleaners.

In all fairness to doctors and their employees, I do think some provision should be made in the National Health Service to put doctors' secretarial and domestic employees on the same footing as the executive councils' employees, the former are just as necessary in the efficient running of the Health Service—I am, etc.

Lincoln

JOAN M ELLIS

### Politics or Medicine?

SIR—I have read with repugnance the report of a speech delivered at Durham by the Minister of Health in which he made an attempt, by quoting infantile and maternal mortality figures for two widely separated years to prove his prowess and success.

I do not question the figures the Minister quoted for the years 1926 and 1946, but I do take exception to the interpretation he chose to put on them. The conceit of taking to himself the credit for the dramatic improvement cannot be excused.

One presumes that the Minister is aware that in the decades he used as illustration were discovered and developed the "sulpha" group of drugs, penicillin, the theory of the rhesus factor and so on. To their aid and to the efforts of the medical profession, whom he chooses to ignore as unworthy of any share

of praise, the betterment is largely due. It is pitiful that at the start of the new Health Service the Minister gives no credit where credit is justly due, but claims it all to himself—I am, etc,

Dundee

W H GOSSIP

### Initial Faults

SIR—I should like to endorse all those excellent letters appearing above signatures on pp 86 and 87 of the *Supplement* of Aug 14. A survey of these letters shows that there is considerable ground for dissatisfaction over numerous anomalies and injustices in the new Service. I would like to ask: Can the B M A do anything about it? I recently heard the Chairman of Council state that it was now more important than ever that we had a strong B M A. The B M A has never in its history been so strong, yet at the height of its numerical strength it proved powerless to prevent the precipitate birth of a service so full of anomalies and injustices. If the B M A is to be the organ which will represent the profession, let it justify its existence and partially atone for its recent blunders by getting these initial faults put right, and put right very quickly. If it cannot do this, it can have no justification for its existence, and I, in common with very many others will be bound to withdraw my support of the Association—I am, etc,

Bridgwater Somerset

J HANWAY BEALE

### Independent Doctors

SIR—One feels that the author of the ingenuous annotation "Independent Doctors" (Aug 14, p 347) must have written with his tongue in his cheek when he states, "If those taking part in this week's talks feel that some kind of 'watch committee' is necessary to represent the interests of those staying outside the National Health Service there would appear to be no reason why such a committee should not be set up for this purpose in the B M A." But in case your annotator should require enlightenment upon this matter, may I be permitted to point out that there is a very good reason why such a body should not be set up within the B M A—namely, that very many, if not the majority, of doctors have lost confidence in the ability of the B M A to represent the best interests of the profession—I am, etc,

East Horsley Surrey

B S GRANT

### Recovery of Fees

SIR—I have been interested to observe the extract from the National Health Service (Pay-Bed Accommodation in Hospitals etc.) Regulations, published in the *Supplement* of July 31 (p 61). Under Section 8 it is stated, "The charges to be made and recovered by a medical practitioner" and later we have the two schedules. Exactly how are these charges to be made and recovered by the practitioner? Is the collection of fees to be made by the hospital or by the practitioner directly? If it is to be the latter, who observes that the 75-guinea limit is not exceeded? I interpret the schedule that the first concerns payments made by patients to the hospital authority and that the second concerns payments made by patients to practitioners.

In my hospital there is as yet nothing known as to how this aspect of the new Service is to work—I am, etc,

Penzance

T D S HOLLIDAY

\*\* The Secretary of the Association writes. It is understood from the Ministry of Health that it is the responsibility of the practitioner concerned to recover his professional fees from his private patients, but that he may come to an arrangement with the hospital management committee or board of governors by which his account is presented to the patient along with that of the hospital.

### The Unattended Telephone

SIR,—Dr H B C Sandiford (Aug 21 p 91) refers to the unmentioned charges for installation and maintenance of the automatic telephone. He also makes mention of the tardiness in the response of the profession to this offer. May I, Sir, being myself an interested party, make some comment on this subject?

The automatic telephone mentioned by your correspondent was developed no doubt to meet certain medical requirements

The modification of this, also mentioned in the article referred to by him, is a smaller instrument, cheaper and designed for more general use and easier comprehension by the average patient. However, without professional demand, I do not see how ancillary charges can very well be reduced on the average, in spite of the smaller machine, useful as it no doubt will prove to be.

What is it we require of a telephone service? Doctors require 'phone coverage 24 hours daily, all or any part of this time, and over periods varying from day to day. Patients require the assurance that their messages will reach the doctor at the earliest, failing which there will be some person to deal with their wants. None of these has the G P O seriously undertaken before, and they certainly will not do so now. What has been done by them before was to intercept an unanswered call and redirect the caller to another, preselected number. This they are definitely no longer prepared to do beyond what they are able now to manage, and this inability, due to the lacks we find so common to-day, has been published at least twice in your columns in the last twelve months.

There has been some reasonable excuse in the past few months for the desultory interest taken in these matters but there is no doubt now that with adequate response from the profession generally there would be great encouragement and progress. Public appeal is useless in the absence of widespread professional support. If official telephone services are inappropriate public attention can be brought to this specialized service only when the number of doctors behind it in any given centre is great enough to permit the making of reasonably accurate claims and conditions. Given wide support at each centre general publicity and advertisement could easily inform the "patient" public where to find attention in case of need—I am, etc

Percall Service Ltd

## HUMAN RELATIONS IN INDUSTRY\*

BY

SIR GEORGE SCHUSTER, KCSI, KCMG, CBE, M.C

1 My approach will be that of a "universalist" rather than a specialist. I shall try to present various relevant considerations in their right total setting.

2 The subject of human relations in industry is attracting increasing attention to-day. There are many reasons for this in the conditions of our time. In the desperate national need for improved production there is a growing appreciation that, since mechanical re-equipment will take a long time, immediate results must be sought mainly in better use of human effort, for which voluntary co-operation is an essential condition.

3 That there should be increased interest is to the good. But there are dangers in a special concentration of interest aroused in this way—first, the danger that the improvement of human relations may be sought merely as a means to an end, and, secondly, the danger that the human factor may be treated as a detached subject for the specialist, as something which can be studied in isolation instead of as part of a total situation for which all share responsibility.

### The Ends of Industrial Activity

4 "What are the ends of industrial activity?" As I see it there should be a threefold purpose.

(1) To achieve "excellence"† in production, which in practical terms means to produce the "right" things with the minimum expenditure of human effort and material resources.

(2) To provide for the human beings engaged in it a satisfactory activity as the foundation of a good life.

(3) To fit in as an important part of a satisfactory pattern of society.

Of course in this imperfect world (certainly as we are likely to find it in our lifetime) there will be no ideal fulfilment of all these purposes. In practical circumstances they may at times be in conflict one with the other in the sense that more emphasis on one may mean less on the others. But no single one of them can be neglected, and the three must be reconciled as best possible.

Let me apply these ideas to the subject of my address in the actual conditions of to-day, and explain my apprehensions of the "dangers".

5 My chief point is that if managers start now to take a human interest in their workers *merely* as a means to an end—merely in order to improve production results—then they will be both wrong and unsuccessful. They will be

wrong because it is wrong to treat human beings merely as a means to an end. They will be unsuccessful because they will be found out. The whole industrial field is bedevilled with suspicions based on past memories. As a result, even the most honest attempts to improve human relations tend to be viewed with mistrust—either as mere dodges to get something extra out of the workers for the benefit of the profit-makers or as signs of a temporary mood "produced by force of circumstances rather than a change of heart" (to quote words recently used to me by a trade union leader).

### Human Relations

6 Good human relations in industry can only be surely founded on the treatment of each individual as a human being of infinite value whose welfare in the highest sense must be regarded as an end in itself. Industrial employment can provide the foundation for this welfare to the extent that the worker can find interest, free self-expression, and happiness in his work, something more than a mere distasteful way of earning a living. To help workers to find this should, therefore, be seen as an essential part of the managers' task in handling human relations.

7 But before I turn to that I want to make two points to show how I see this central purpose in its relations with the other two purposes in my list and in the total picture.

If to-day there is a danger that the "central purpose" will be debased or distrusted by being seen merely as a means to getting increased production, there is a converse danger that concentration on creating good human relations may tend to make the importance of *efficiency* undervalued. It is not enough for managers to be human and kind-hearted. Their efficiency—technical, commercial, administrative—is also necessary. Without that, "excellence in production," the first in my list of three purposes, cannot be achieved. And that is vital. If British industry fails in the quantity and quality of its production our whole order of society may break down. But there is more in it than this. Efficiency in management (both technical and commercial) is an essential condition for good human relations. As Sir Stafford Cripps said the other day, 'Co-operation rests on confidence, and confidence rests on competence.'

### Social Setting

8 The other point I want to make is concerned with the social setting—that is to say, with the third heading in my list of ends. It is impossible to have the right atmosphere of interest, happiness, and co-operation in industrial employment if the demands which it makes on the individual are in conflict with his social setting or his aspirations as affected by that setting. If his work makes demands on his time and energies which prevent his playing his due part as a member of his family or of other social groups if,

\*Read in opening a discussion in the Section of Occupational Health at the Annual Meeting of the British Medical Association, Cambridge 1948.

†"Universality does not consist in knowing as much as possible, but in seeing the relation between things. The universalist man does not wish to know everything but to grasp what is essential. Suddenly in a moment of blessed rapture he is vouchsafed a glimpse of the whole" (Walter Schubart).

‡I use 'excellence' in the sense of the Greek word *arete*.

in his outside society, his interest in his work brings him not honour but low regard or even ridicule, that will set up internal conflicts militating against good work or happiness in it

9 Let me sum up what I have been trying to say. First, the greatest need of our modern industrial society is to make industrial employment something which is, and is seen as, an essential part of a satisfactory human life (individual and social), *not* a cause of conflict or an evil burden to be escaped from or reduced as far as possible. Secondly, this purpose will not be attained unless managers are both single-hearted in their pursuit of it and also efficient at their production job. Thirdly, industrial employment must fit in harmoniously with the workers' social setting.

10 These conceptions are absolutely fundamental. They are fundamental for the individual because without satisfying work—free expression in work—there can be no sure foundation for his physical, mental, or spiritual health. They are fundamental for society because somehow or other industrial employment must be fitted into the total pattern of society as part of a balanced and harmonious whole. (We have hitherto failed to evolve a satisfactory pattern of an industrial society.) They are fundamental for economic achievement because, unless industrial employment can fit in with a satisfactory individual life and a satisfactory form of society, there must always be friction and loss of effort in industrial employment.

#### Practical Arrangements or Methods

11 What then are the practical arrangements or methods which will help to make industrial employment a satisfying creative activity which fits in with a satisfactory pattern of society? This is what I see as the main question. But there is perhaps a prior question which must be answered. Is the end stated in my question attainable at all? Is my whole approach unrealistic? Doubtless many people will think it is. Certainly it is a commonplace to say that conditions of modern industry—with its mechanization, mass production, breakdown of skilled jobs into repetitive unskilled or semi-skilled operations, and so on—have made it impossible for the bulk of manual workers to find in their daily work a soul-satisfying activity. I do not deny the difficulties, but I think they are exaggerated. I believe that modern industry offers opportunities for new kinds of interest to offset the loss of craft interest. Nevertheless there is of course here a crucial question, and we need to know much more on many aspects of it—how jobs affect different people, what proportion of drudgery is tolerable or, indeed, may even be desirable as a sort of "roughage" in our mental and spiritual diet, how jobs and machines can be designed with better regard for the human beings who have to do or operate them, how far, even from a production point of view, it is right to break down jobs into separate operations, at what point there begins to be a loss of effort from boredom or monotony which counterbalances any benefit from simplification, etc., etc.

12 Taking account of all these considerations I find myself brought to certain practical conclusions.

First, the less the creative satisfaction in the work itself the greater is the need for supplementing it, with satisfactions in comradeship, in understanding the common purpose of the working team, and in the use of leisure.

Secondly, at the very lowest, industrial work should be seen as a dignified activity, a necessity of nature, a condition of self-respect—not a definite evil imposed unnecessarily by the selfishness or incompetence of others. At the very lowest, even though it may not be itself a strong positive element of satisfaction in a good life, it must at least afford a foundation for that and not be an obstacle to it.

13 With these reflections I turn back to my main question—"What are the practical methods and arrangements which will help to make industrial employment a satisfying creative activity in a satisfactory pattern of society?"

The first thing to make clear is that there is no single universal prescription, no code or set of rules which an industrial leader can adopt with the comfortable feeling that he has got the solution for all the problems for the rest of his life. Indeed it is an essential point in my answer to say "Beware of cut-and-dried systems, the problem is one which needs never-ending attention, fresh effort every day, courage to face disappointments, flexibility to adapt methods to the varying conditions and different classes of work or worker, patience and sympathy to understand each single individual with his infinite variability. (For it all comes down to the individual in the end)."

14 There is another reason why no single answer can be found to my question. One cannot generalize about British industry. There are such great variations between one unit and another, one industry and another, one district and another.

15 Yet this recognition that there can be no finality and that there must be constant variety and flexibility of method should not blur the conception of the guiding purpose nor discourage efforts to keep day-to-day practice under continuous scientific observation. On the contrary, the very nature of the case increases the need for clarity of purpose and patient interpretation of experience.

#### Negative Obstructions

16 When one turns to consider practical measures, I believe that the chief emphasis for immediate attention should be placed on removing obstructive influences.

I say this for two reasons. First, I believe in individual liberty as a fundamental principle, and I regard freedom of expression in work as the most essential element in this. Therefore I favour the sort of method which as far as possible leaves the individual to work out his own salvation. Secondly, I believe that the ordinary people of this country are fundamentally decent and ready to make the best of things.

Without arguing these points fully I will state my own belief that the problem of creating adequate satisfaction in work would not be too difficult if certain negative and obstructive influences could be removed. Our chief trouble to-day is that there are so many of these which prevent the individual giving his normal instinctive response. There are the suspicions which I have already mentioned based on memories of the past. There is the fact that the individual worker approaches many questions as a trade unionist, and that the whole trade union organization grew up as a war organization to fight for one side against another. There is the fact that, in spite of recent improvements, material conditions—housing conditions, factory conditions, methods and tools of work—are in many cases such as to make it very hard for the individual to see his work as a satisfying activity consistent with a good social life. There is the fact that for many the margin for security, leisure, and good times is still inadequate.

These are all general considerations. But in every particular situation there will be found particular obstacles. I could give many illustrations where the influence of individuals—individual tactlessness, or jealousy, or suspicion—is holding up progress and co-operation.

There is need to deal resolutely and patiently with all these negative obstructions, general and particular. That requires tactful handling of individuals but in the long run success will depend on getting the right guiding purpose clearly conceived and widely accepted.

17 If, then, my remarks are to have any practical value I must give more concrete content to my definition of the guiding purpose. In the simplest terms I have stated this as the purpose of making the individual happy in his work. But of course one cannot consider the individual in isolation. His work must fit in with that of his fellow workers and his relations with them form an essential part of the conditions affecting the result.

### Essential Points

18 The best way to bring out the kinds of action which are necessary is to make a list of the main points which are essential for a satisfactory total situation. Approaching the matter in this elementary way I would say that the guiding purpose should be to create in each industrial undertaking a satisfied healthy community of individuals

each interested in his own job,

feeling that he has an individual responsibility for it and some freedom for expressing himself in it,

all working together as a team,

with a sense of joint responsibility, understanding the place of their own work in the total purpose. Satisfied that this total purpose has a recognizable social value.

Working in healthy conditions

at tasks which give the satisfactions of skill in performance and of physical effort accomplished without overtaxing strain,

and finally satisfied that the proceeds of the whole joint effort are fairly divided.

This is a very elementary statement. It includes eleven conditions, all of which are familiar.

The much more difficult question, however, is by what means these conditions can be established.

19 I will start with two general or overriding conditions.

(1) *Organization*—There must be a good organizational structure capable of supporting the ideas embodied in my list of eleven conditions. Otherwise anything done about them will be mere camouflage with no genuine validity. In particular there must be a clear conception of the function of every individual working in the organization, and a clear chain of authority. Each must know *for what* and *to whom* he is responsible. Otherwise the idea of joint responsibility will not work and there will be a constant risk of confusion and frustration. This of course has a bearing on the position of industrial medical officers.

(2) *Enlightened Opinion from the Floor Upwards*—It is in the creation of this that I see the essential purpose of joint consultative methods. I cannot, as I should like to do, deal fully with all that is involved in the successful application of these methods. But there is one point which I must make. Joint consultation is normally and quite correctly, seen as a method for bringing about a sharing of responsibility. But there are some current fears (and aspirations) about this idea of sharing responsibility which I think are based on a misconception. As I see it sharing responsibility ought not to mean getting responsibilities either confused or divided. It ought not to mean that the workers claim a share in management in the sense of usurping responsibilities which properly belong to management. Nor conversely, should it mean management trying to put on to the backs of the workers responsibilities which it should carry itself. (I mention this latter possible interpretation because I have found that in certain cases where management has carried ideas of joint consultation very far, apprehensions of this kind are actually voiced by the workers.) What it should mean is on the one hand that every worker should have the chance to put forward ideas on the arrangements affecting his own job and feel that he has some freedom in the actual handling of that job and,

on the other hand, that in doing this he should have an understanding of the central purpose of the whole organization.

The chief executive officer, just like a military commander, has certain responsibilities for leadership and decision which he cannot devolve. There should be no weakening in his leadership and authority. But that does not mean that he should not help his subordinates to understand the reasons for his decisions, or that when it comes to settling how operations (whether in military action or industrial production) should be carried out he cannot get valuable ideas by consultation with his subordinates right down to the rank and file. The essence of good organization is (as Elton Mayo has well put it) to ensure that every decision is taken at the level where it can be most rapidly and effectively taken. And the essential point is that decentralized decisions cannot be well taken unless they are based on sufficient understanding of the central purpose. It is in these conceptions that I see the essential value of joint consultative methods, and I want to see medical officers brought into the whole process of joint consultation.

### Role of Medical Officers

20 I pass from these two overriding conditions to consider a few particular points in regard to which, as I see it, medical officers have a most important part to play.

(a) First, there is all that is involved in *fitting the man to the job and the job to the man*. This of course has two aspects: on the one hand, selection and training of the man, on the other hand, design of the job and the tools for doing it. The two aspects are interdependent. I have already in my introductory remarks stated my view that much more study is needed of the psychological reactions of different kinds of manual work (taking into account the different aptitudes and characters of individuals). Based on such studies, much more thought should be given to the arrangement of production processes and the design of machines so that they may be best adapted to the human beings who have to work them.

We can all think of types of machines which must tend to "dehumanize" those who work them. There are many other aspects of this question. One of particular interest is the effect of ageing on industrial capacity. Increasing age may increase the value of certain capacities and diminish the value of others. Jobs should be designed to take account of this. This is important not only for the sake of the individuals concerned but also for general morale and production results. For example, new methods of work measurement and control introduced by some progressive firms are undoubtedly "hotting up the pace" of work, so that the older men feel at a disadvantage. Yet some of the older employees, say in the 50's, may in many ways be the most valuable elements in a works community.

Another aspect is when a man suffers from some special disability which disqualifies him for certain jobs—for example, colour blindness. Careful human consideration of the individual is necessary in such cases, consideration which will discover what he is best suited for and what openings can be found. In all this of course the medical officer can play a great part. His knowledge can help in the designing of machines as well as in finding out for what a man is best fitted. The positive helpful approach is needed here.

(b) A second point that I specially select for mention is *human understanding of each individual*. As I have already said, it all comes down to the individual in the end, and I regard it as a vital feature of a good organization that every worker should have, in the chain of authority above him, someone who can give appreciation of good work and who also understands him as an individual—not only in his work but in his interests and all the outside influences which affect him.

This point is of great importance in itself, but also for another reason. I see it as closely connected with discipline. There must be discipline, but firm discipline cannot be fairly exercised without an understanding of the individual and all that affects his conduct.

(c) Thirdly I come to an obvious point—health. This—and I mean positive health in the widest sense—is clearly a vital factor affecting the will to work and happiness in work. It is so essentially the subject of your conference that I will not enlarge upon it in this introductory talk.

21 I have, as already explained, selected these three points because I see them as matters which closely affect the position of medical officers and in regard to which they have a special part to play

### Outside Influences which may Help or Obstruct

22 To complete my sketch of the general framework I must make a short reference to the outside influences which may help or obstruct the fulfilment of the purposes of which I am speaking

Of all the outside influences that of the trade unions is the most obviously important. Here there are crucial questions to-day. What is going to be the trade union attitude to firms which are genuinely trying to create a sense of joint responsibility, community, and loyalty? Will trade union officials fear conflict of loyalties and obstruct? Or will they use their powers to encourage such firms? I believe the national trade union leaders are likely to take a broad and sound view on this question, but the attitude of subordinate officials in the districts may be different.

Apart from the trade union there are of course many other outside influences to take into account, political influences (under which heading one must put the Communist influence, which may be based on a desire to see the whole existing system break down), social setting and home conditions, the locality and its traditions, education (with particular reference to the effect on the general attitude to manual work of extending the statutory school-leaving age to 16), memories—good memories for bad things—an obstructive influence chiefly in the old industries like coal-mining or cotton textiles which got their form in the early days of the Industrial Revolution and have been through bad times, and, finally, habits and the effect of world wars on breaking habits.

### The Parts to be Played

23 What I have said hitherto about ends, methods, and outside influences has all been intended to lead up to the practical question, How should the various people concerned—executive officers, functional officers, rank and file—play their parts in the field of human relations?

In turning to this question of the parts to be played I come to the second of the two current dangers to which I referred at the beginning—the danger of regarding the human factor or human relations in industry as subjects which can be considered in isolation or left to specialists.

Everything to do with human relations and attitudes must be seen as an integral part of a total situation. Everyone engaged in industry in any capacity should be concerned with these questions all the time. When a production programme is being planned, when plant layout is being discussed, when new machinery is to be installed, or new designs of products are to be introduced—in every decision affecting every aspect of work—the reactions on the human being concerned should be taken into account.

24 For this reason I want specially to stress the importance in regard to this matter of human relations of having the right conceptions of the position of specialists or functional officers,\* and of the role of detached scientists and scientific research. Scientific research into human factor problems cannot be carried out in laboratories, and the chief value of the “scientific approach” in this field lies in the application of scientific method to the continuous daily study of the life processes of industry—industry being seen as a body of human beings working together for a

specific purpose. Special pieces of research work may be of value but they must be carried out on the spot in industry and must be applied to total situations, treating the unit investigated as a functional whole. Even these *ad hoc* investigations alone can make only a minor contribution. The major need is for continuous observation in the course of normal work.

### Industrial Medical Officers

25 This brings me to the position of industrial medical officers considered as a class of specialists who have a most important part to play in the matter of human relations. I will venture some ideas I would like to see accepted.

(i) The aim should be essentially constructive—the creation of positive health rather than merely the cure, or even the prevention, of disease.

(ii) A full-time medical officer should be employed and should be treated as a member of the management team. He has just as much right to this as the chief engineer.

(iii) As members of the team, works medical officers should take part in all joint management discussions and should know broadly what is happening in the firm as a whole. The medical view should be heard on every point in the total planning of premises, plant, production, etc.

(iv) The fact that a medical officer is a specialist should not exclude him—or indeed any other specialist—from eligibility for appointment to the highest administrative posts, if he desires that, and if he has the necessary abilities and qualities.

(v) If, on the strength of this broad conception of the human responsibilities of management, the medical officer is included in the management team he must himself have similar broad human conceptions of his own work. He must see the men and women with whom he comes in contact not as ‘cases’ but as human beings. He must be interested in all that affects them. He should have psychological insight into the material with which he is dealing.” I take these last words from a paper read recently by Dr Donald Stewart.

26 In what I have said I have been putting forward the broad conception of the works medical officer as a member of the management team. This I see as necessary for the achievement of the main purpose in human relations. But it is also necessary if the medical officer is to be able to do his own daily tasks properly.

“For instance”—to quote from a managing director’s letter—“I well remember our own medical officer having a check done on the carbon-dioxide content of one of our shops and finding it somewhat too high for his liking. He examined the shop and found that by extension of the flue-pipes on certain die-casting machines it seemed probable that this inert gas could be more efficiently exhausted. This was done, and overcame the problem quite simply. I am sure that the less-trained man would have demanded ‘a much more efficient ventilation system,’ which would have involved enormous expenditure and which would then, by its nature, have increased the heating problem in the shop, giving rise in turn to the need for better heating arrangements, but leaving the problem of draught behind it still.”

27 Points like these are of considerable practical importance but I am more concerned with the contribution which the medical officer can make towards achieving what I have described as the essential task of management in the field of human relations—to create conditions in which people<sup>†</sup> can find interest and happiness in their work. The matching of the worker and the job is part of the task on which the good medical officer can make the decisive contribution.

### Human Contacts

28 Beyond this I am impressed with the special opportunity which the good medical officer can have in the whole field of human contacts—especially under the heading of

\* It has been well said that the general manager should himself be a specialist on human relations. But this does not mean that a personnel officer should not be included among the functional officers.

appreciation of the individual. He has the chance to make close contacts with workers without arousing any suspicions of ulterior motives. He has an opportunity to gain their confidence and to get to know their personal problems and all the outside influences which affect them. And at this point I want to express the view that, when the general relations between management and workers are good, there is no ground for the fear that the medical officer will become suspect because of his association with management or he is treated as a member of the management team. On the contrary, I believe it is true to say that, because he is a doctor who has access to and can influence management, the workers will go to him with problems which would otherwise never come to light.

In that connexion I am specially impressed with the opportunities of the medical approach in industries where the psychological atmosphere is abnormally difficult—coal-mining for instance. I have in mind, for example, the investigation which is now being made into nystagmus by Professor Brown, working from Durham University. All his arrangements have been made with and are supported by the local trade union organization.

In all this field one has to remember that psychological investigations—any research projects which can be regarded as a sort of “psycho-analysis” of the workers—are apt to arouse acute suspicions. On the other hand, investigations made for a clear purpose which the workers can readily understand are welcomed and can evoke co-operation.

### Full-time Medical Officer

29 I have advocated a service for purposes which could not be met by occasional visits from an outside practitioner but which depend on a full-time medical officer treated as an integral part of the management team. I have advocated such a service for the whole of industry. But what is the present position? I believe that, when Sir Thomas Legge arranged the first conference of industrial medical officers in 1921, only 20 could be found. Now I am told that there are ten times that number—about 200, supplemented by about 700 part-time officers. This obviously therefore covers only a tiny patch of industry. There are about 150 000 factories in this country. The vast majority of these of course are very small, but 15,000 are advanced enough to have canteens.

Obviously, therefore, my ideal is a very long way off. But is it really practicable? Would it cost too much? How could it be provided by small concerns which could not afford the service of a full-time medical officer of their own?

30 I do not know whether there has been any comprehensive investigation on these questions. I can do no more than raise them as questions for discussion. As to cost, I have been interested in some articles by Dr Gange, the chief medical officer of the Glacier Metal Company, which showed that the annual cost in an engineering firm employing about 3 000 worked out at 22s per head. Dr Gange compared the total annual cost in this case—£3 300—with the normal rate of expenditure on the maintenance department of an industrial undertaking of that kind and size, which he put at £20,000 to £50,000. Certainly if these figures are a true guide there ought to be no obstacle on financial grounds.

As to the provision of services for the smaller firms the solution would clearly have to be found in some kind of grouping arrangements.

31 I pass now to another question which has been in my mind throughout and which has very wide implications—namely “How do my conceptions of a medical service provided by individual firms fit in with Government policy,

Factory Acts, the factory inspectorate, national health policy, and the new State medical service scheme?”

I will only venture on a few observations on what might be the effects if, over the whole industrial front, there could be developed the kind of works medical service which I have advocated.

(i) It could be fitted in with, and be a most valuable supplement to, anything that can be done by the Government by way either of factory legislation or of a State medical service.

(ii) The kind of research work into industrial health, fatigue, etc., which has for many years been sponsored by the Medical Research Council would have a much greater chance of getting effective application.

(iii) There might be considerable economies and a much better adjustment between what is attempted or prescribed and the resources that are available. The example that I quoted from a works medical officer in a particular factory seems to show that, if such advice were always available, good practical results might be achieved at much less expense than if the same results were aimed at by rigid regulations.

32 Lastly, it is important to observe—and this is in harmony with all that I have been saying to-day—that a works medical officer could not possibly fill the place I envisage in a management team and in the confidence of the workers unless the whole attitude of management is such as to have already won their complete confidence. Unless there is confidence based on genuine consideration for the individual worker medical advice and medical inspection, if seen as part of the “management” set-up, are apt to be distrusted and feared.

### A Request

33 At the end of this unduly long paper I want to put forward a practical request. I imagine that I have been asked to address you because I am a member of the Government's new Committee on Industrial Productivity and chairman of its Panel on the Human Factors affecting productivity. From a panel of a committee which is only advisory and which is dealing with such an all-embracing and elusive subject as the human factor it is not easy to produce effective action. In the first place we have inaugurated a series of research projects covering such matters as joint consultation methods, the training and selection of foremen, work design and measurement of human performance, effects of ageing on industrial productivity and allocation of work, the effect on production of simplifying operations by job breakdown, methods for dissemination and assimilation of existing knowledge, etc. We are also planning some investigations into particular industries. Apart from these research projects we hope to be able to stimulate action of a more practical nature designed in various industries or areas to encourage the exchange of knowledge and the raising of average standards of productive efficiency nearer to the level which progressive firms have shown to be possible.

If any effective action is to result, that will depend largely on the measure of active co-operation which can be got from industry—both management and trade unions—as well as on the closeness of contact which can be established so as to reveal opportunities. I have from the beginning felt that most valuable aid could be got from industrial medical officers, and, without taking further time in explaining the position, I want to ask this conference whether it would be possible to form a group of industrial medical officers with whom my panel could discuss possibilities.

### Conclusion

34 I will add one final word. All that I have said has been framed to lead up to certain considerations about the position of industrial medical officers as part of the manage-

ment team I have naturally therefore tended to speak of human relations in industry in terms of the attitude of 'management' to workers. But I do want to emphasize that to think in these terms alone is quite inadequate. Human relations in any case are a two-way business, and the success of anything that can be done depends not merely on how management behaves to workers but on how the individual workers respond. But there are some things which seem to me to be clear beyond all doubt.

The first is that management if it wants to retain leadership should not argue about who is to blame, but should itself accept responsibility for giving a constructive lead.

The second is this. To-day we must all make a choice between two alternative ways. Are we to go forward or back? Are we to play down to the worst motives—fear and greed—or play up to the best—pride in the job, a sense of responsibility, a desire to act a worthy part in life? I have no doubt about what is the right answer, whether viewed as a matter of practical expediency or moral rightness. The only hope is to go forward, and the chief task is to clear away the obstacles which hinder the better motives having free play.

## RAT-BITE FEVER DUE TO STREPTOBACILLUS MONILIFORMIS

BY

I R W LOMINSKI, MD  
A STEWART HENDERSON, MB, ChB

AND

J W McNEE, MD, FRCP

(From the Departments of Bacteriology and Medicine  
University and Western Infirmary of Glasgow)

After many years of difficulty and confusion it is now clearly established that rat-bite fever may arise from two distinct infecting agents. Not all cases are due to actual rat bites, and in the absence of a clear history clinical differentiation of the two types is generally impossible and bacteriological evidence alone conclusive. Infection with *Spirillum minus* (originally named *Spirochaeta morsus muris* by its Japanese discoverers in 1916–17) is the commoner variety, and very many cases are on record. Infection with *Streptobacillus moniliformis* is much rarer, and Altemeier, Snyder, and Howe (1945) could trace only 17 examples published in the United States. This micro-organism was first discovered by Schottmuller in 1914, and classified by him as a streptothrix. The present name was first applied by Levaditi, Nicolau, and Poincloux in 1925, who isolated it from a laboratory worker, who, incidentally, had not been bitten by a rat.

The whole story of the elucidation of rat-bite fever of both varieties, including the relations of the streptobacillus to Haverhill fever and to the organismal cause of pleuropneumonia in cattle, is very fully reviewed by Brown and Nune-maker (1942). The incubation period of the spirillar infection is usually longer (seven days or much more) than in the streptobacillary disease (three days or more), but the period is so variable that only a clear history of a bite followed by a long interval before illness develops might clinically suggest the spirillar variety.

The newer arsenical drugs were quickly recognized to be very effective against the *Spirillum minus*, but the streptobacillary disease ran a protracted and serious course until the advent of penicillin.

This short account of a single case is intended to draw renewed attention to the *Streptobacillus moniliformis* as a

cause of rat-bite fever in Britain, to illustrate the methods of rapid bacteriological diagnosis and the chief cultural characteristics of the organism, and to emphasize the dramatic effect of adequate penicillin treatment.

### Case History

The patient was bitten on the right thumb while handling a hooded rat prior to an experimental operation. His hands were 'scrubbed up' at the time, and the wound was at once thoroughly washed and a sterile dressing applied. The wound appeared to be healing normally, but on the morning of the third day (i.e., within 48 hours of the bite) he felt very ill on waking. A severe rigor followed almost immediately lasting half an hour, with fever beginning at 101° F (38.3° C) and reaching 103° F (39.4° C) by evening, and associated with severe pains in the limbs and back. Fever continued throughout the following day, with, in addition to generalized muscular pains, severe pain and redness over the right elbow at the olecranon. This first attack of fever lasted for about 48 hours, and on the morning of the third day after the fever started the patient felt much better, except for the painful right elbow. On this day a scanty rash appeared on the dorsal aspects of the feet. He continued to be fairly comfortable for 48 hours, when the first bout was completely repeated, with high fever (103° F) and severe shooting pains particularly in the region of the right scapula. The rash also spread to involve the back, forearms and feet. He was admitted to hospital on the seventh day of illness about 12 hours before the end of the second attack.

On admission the patient looked very ill, with a temperature of 103° F. A fairly extensive maculo papular rash (no petechiae) was present, most abundant on the forearms, hands, legs, and feet, and less extensive on the forehead and body. The spleen and lymph glands were not enlarged. The leucocyte count was 10,400 (85% neutrophil polymorphs, 14.5% mono nuclear cells).

The laboratory investigations are given separately for clearness, but as soon as blood films proved negative for *Spirillum minus* and blood cultures had been taken penicillin therapy was started, with the idea quickly proved correct, that the infection might be due to *Streptobacillus moniliformis*. There was no scarcity of penicillin, and 500,000 units were given intramuscularly at once. By next morning the temperature was normal, but penicillin was continued intramuscularly in heavy dosage for seven days a total of over 12,000,000 units being administered. The patient quickly recovered without fever or relapse and has remained completely well.

### Laboratory Investigations

The clinical history suggested rat-bite fever, and the following investigations were rapidly carried out after the patient was admitted to hospital. Six fairly thick blood films were stained and examined for the *Spirillum minus* with negative results. Two guinea-pigs and two mice were inoculated intraperitoneally with 1 ml of heparinized blood from the patient, the results are referred to later. Blood cultures were made by dividing 20 ml of the patient's blood among three flasks containing heparinized horse-heart digest broth, and were incubated at 37° C. After 18 hours a few fluffy granules were seen floating on the top of the layer of sedimented red blood cells, and these were found to consist of tangled chains of pleomorphic coccobacilli. They stained feebly by Gram's method, but strongly with Leishman, Giemsa polychrome methylene blue and carbol fuchsin stains. Subcultures were readily obtained in glucose horse serum digest broth and on Loeffler's serum medium, while after incubation for a further 48 hours the original cultures showed a mass of "cotton-ball" colonies covering the layer of red cells in the flasks.

The diagnosis was now made but further bacteriological observations may be briefly but accurately summarized.

*The Micro organism*—This was pleomorphic slender, motile and non-sporing, occasionally occurring as short rods but mostly arranged in chains of coccil or coccobacterial bodies or in long continuous filaments spreading across several microscopical fields. All of these forms were present simultaneously, and the long filaments were so interwoven that the question of

branching remained undecided. In young cultures on Loeffler's serum spindle-shaped rods and filaments predominated, the latter being shorter than in fluid media. The filaments also showed central, terminal, or subterminal swellings (moniliform bodies) similar to those seen by one of us (I.R.W.L.) in Levaditi's laboratory in 1936. It was noted that the moniliform bodies tended to disappear in older cultures.

**Staining Reactions.**—Poor results were obtained with Gram's stain, but on the whole in very young cultures the organism tended to be Gram-positive and in older cultures Gram-negative. With the other stains previously mentioned the staining was irregular, the moniliform bodies being coloured more intensely than the filaments. When stained with Ziehl-Neelsen's carbolfuchsin the organism was not acid-fast.

**Characteristics in Culture.**—On solid media no growth occurred on ordinary agar, very scanty growth on 5% blood agar, good growth on 25% horse-serum agar, and abundant growth on glucose-serum agar and Loeffler's serum. The colonies were at first small and translucent, but became granular and rough after several days. Even after 24 hours a number of the colonies were of R type. In deep glucose serum agar shake cultures mulberry-shaped colonies appeared which were not limited to the aerobic zone. The organism is thus aerobic but a facultative anaerobe. Growth did not appear to be stimulated by increased carbon dioxide pressure. In fluid media abundant growth occurred, as already indicated, when serum and fermentable carbohydrates were present. The sugar reactions were as follows: acid but no gas from glucose and starch, slight acid from lactose and maltose, no indole formation, gelatin not liquefied. In fluid media containing carbohydrates subcultures were found to be essential every 48 hours. In carbohydrate-free media the organism can remain alive for five days but is dead in seven days. It is killed by exposure to 60° C for 20 minutes. The organism isolated was found to be very sensitive to penicillin, all growth being inhibited by 0.01 unit of the drug per 1 ml of medium.

**Animal Inoculation.**—The organism is pathogenic for mice, and both animals inoculated intraperitoneally with 1 ml of the patient's blood died in 9 and 11 days. Similar inoculations from 24-hour cultures (0.5 to 1 ml) caused death in four to six days but no characteristic lesions were observed at necropsy, although heart-blood cultures were positive. Both guinea-pigs and rabbits seem to be insusceptible.

Two additional points of interest may be noted. Attempts to demonstrate agglutinins both in the patient's blood and in the susceptible animals, failed, for the organism was auto-agglutinable even in media free from carbohydrates. The whole stock of hooded rats from the cage containing the original culprit was examined and *Streptobacillus moniliformis* was obtained by swabbing the nasopharynx in seven out of the 10 rats examined.

### Discussion

There are records of at least five patients previously treated with penicillin but their illnesses occurred in the time of penicillin scarcity and a much smaller dosage was employed. Kane (1944a, 1944b) reported the first case from Belfast, in which a positive blood culture was obtained only on the 25th day of illness. Gold therapy was tried without success and penicillin was first used on the 62nd day, just after the beginning of a bout of fever. In all 200,000 units were injected over 48 hours, but within 12 hours after only 60,000 units the fever vanished and convalescence was uninterrupted. Weber and Favour (1945) began penicillin treatment of their patient on the 13th day, using at first 100,000 units a day, reduced to 50,000 units on the third day and continued for 10 days. Fever was abolished only on the seventh day. Altmeier, Snyder, and Howe (1945) gave 302,500 units over 8½ days to a child aged 10 months, 212,500 units to a child of 2 years, and 132,000 units over five days (all the drug available) to a child of 4½ years. Cure was immediate and complete in the first and second cases but the third child relapsed four days after penicillin was discontinued and blood culture again became positive.

### Summary

A case of rat-bite fever due to *Streptobacillus moniliformis* (Levaditi) is reported, developing 48 hours after the bite of a hooded rat.

Treatment with penicillin was completely successful, the disease being cured at once. Much larger dosage, probably excessive, was employed than in the few cases previously described, but the illness was severe and relapse had occurred in the days of penicillin scarcity.

The methods of diagnosis and the characteristics of the organism isolated are briefly described.

## A CASE OF ACUTE DERMATOMYOSITIS

BY

J. MacD. HOLMES, M.D., M.R.C.P.

Physician, Staffordshire General Infirmary  
Consulting Physician, Crewe and District Memorial Hospital

Acute non-suppurative myositis involving several muscle groups is a rare condition and deserves special notice when it occurs. It was first described in 1887 almost simultaneously by Wagner, Unverricht, and Hepp, but little has been added to our knowledge of the pathology of the condition since that time. The case recorded here is one of the very few in which an organism that might be regarded as causative has been isolated.

The chief clinical features of the disease are widespread oedema of muscle groups associated with intense pain and tenderness, fever, and often inflammatory lesions of the overlying skin. Unverricht coined the term "dermatomyositis" to describe the disease with cutaneous lesions, but this has since been applied to a large and ill-defined group of skin affections associated with muscular swelling or atrophy and with wide variation in the severity and duration of symptoms. Probably some of these are aetiologically different from the acute polymyositis under consideration, but it is possible that allergic sensitivity may be a common factor.

### Pathology

The clinical and histological features of dermatomyositis of the acute type suggest that it is infective in origin, but organisms have very rarely been isolated and the standard textbook descriptions of the disease state that the aetiology is unknown. Deák (1931) isolated a haemolytic streptococcus in five cases of "acute haemorrhagic myositis," and Karelitz and Welt (1932) found a haemolytic streptococcus in blood culture shortly before death in one case. Other attempts to demonstrate a causative organism have been unsuccessful. Therapeutic evidence of an infective cause has recently been furnished by the successful treatment of the condition with sulphonamides and penicillin. Clark (1946) reports two cases—one treated with sulphonamides and the other with penicillin. Friedmann and Por (1947) also describe a case successfully treated with penicillin. In none of these, however, was an organism isolated from blood cultures. My case appears to be the first in which an

organism has been grown from a biopsy specimen of muscle

The affected muscles are usually soft and friable and may be adherent to the surrounding skin and subcutaneous tissues. Later they may become indurated and scarred. The muscles are severely oedematous in the acute stages and areas of haemorrhage may be seen. The skin usually shows macular or petechial haemorrhages and a variable degree of inflammatory infiltration and oedema.

Microscopically there is extensive degeneration of muscle fibres and infiltration with lymphocytic, mononuclear, or polymorphonuclear cells. Occasionally eosinophilic infiltration is seen. The infiltration is usually perivascular in distribution and oedema is intense. The degree of inflammatory change varies with the severity and stage of the disease. In the late stages the muscle fibres may be entirely replaced by fibrous tissue, with perhaps a few areas of cellular infiltration—the picture of "myositis fibrosa". Occasionally the inflammatory changes involve the walls of blood vessels. In some cases the myocardium and muscles of deglutition are affected.

The blood picture is variable. In many cases there is no leucocytosis even in the acute phases of the disease, but in others a moderate or even high polymorph leucocytosis occurs. There is often a moderate degree of splenomegaly.

#### Differential Diagnosis

The clinical picture, once seen, should be unmistakable. The only condition which at first sight may give difficulty is trichiniasis. The disease was called "pseudo-trichinosis" by Hepp in 1887, but a high degree of eosinophilia is an almost invariable accompaniment of trichiniasis, and microscopical examination of a piece of excised muscle will usually reveal encysted forms of *Trichinella spiralis*. The skin lesions may suggest a diagnosis of the so-called Stevens-Johnson syndrome or of acute lupus erythematosus (Libman-Sachs syndrome), but myositis is not associated with these conditions. Polyarteritis nodosa may have to be considered in a few cases, particularly as some degree of myositis may occur in this disease as well as skin lesions. There should be no difficulty in distinguishing the disease from acute suppurative myositis.

#### Prognosis

The disease has had a high mortality in the past, but few cases have been recorded since sulphonamides and penicillin have been available, and it seems probable that chemotherapy may change the outlook considerably. Recurrences after apparent recovery are common. Many of the patients who survive are left with muscular atrophy or contractures and scleroderma. It is possible that myositis fibrosa is a terminal stage of the disease. Calcinosis is said to be a sequel in some cases. When death occurs it is usually due to involvement of the muscles of respiration or deglutition and sometimes of the myocardium.

#### Case Report

A boy, aged 15, was admitted to Crewe and District Memorial Hospital on Feb 16, 1947. The illness had started seven days before with sore throat followed by pain in the right ear. A few days later a painful swelling appeared in the right arm above the elbow, with oedema of the right pinna and bulging of the right eardrum, red tonsils and fauces, and slight cervical adenitis. The right arm was grossly oedematous from wrist to shoulder. Some swelling was also present in the left arm above the elbow, with extreme tenderness. Temperature 101° F (38.3° C), pulse 120, respiration 24. No cardiac murmurs, blood pressure 125/75, urine normal. Leucocytes 30,000 per cmm—polymorphs 80%. Penicillin, 20,000 units three-hourly, was begun. The muscular swelling spread rapidly to both legs and the face,

and the limbs and trunk became covered with a macular erythematous rash and scattered purpuric patches. Many of the purpuric areas became confluent, and as they faded more appeared. The play of the colours known as erythema iris was seen in the skin lesions. Bullae containing serous fluid appeared on the legs from time to time. The spleen became palpable and tender during the second week of the illness. The patient was immobilized by intense pain, which was only partly relieved by morphine. No improvement occurred until March 3. After this the skin lesions faded, leaving a brownish pigmentation. Pyrexia of 101°–102° F (38.3°–38.9° C) continued and gradually returned to normal on March 28. Penicillin was discontinued on March 16, a total of 3,300,000 units having been given. On March 25 the leucocytes were 5,000 per cmm—polymorphs 65%. Blood cultures were sterile on three occasions—once before treatment with penicillin and twice during treatment. Culture of fluid from a bullous skin lesion was also sterile. The patient was discharged home on April 16. The muscles of his arms and legs were very wasted and some contracture at the knees and elbows was present. Massage and exercises corrected these deformities, and by July 1 he was able to work as a packer. The muscular volume had returned to normal and there was no loss of motor power.

The patient was again admitted to Crewe Hospital on Sept 20, 1947, with a severe recurrence of the polymyositis, similar to the first attack, but more intense. The spleen was again enlarged and tender, and the polymorphic skin lesions more widespread. Temperature 103° F (39.4° C), pulse 120, respiration 24. Blood culture was again sterile and remained so after incubation for 18 days. Leucocytes amounted to 25,600 per cmm—polymorphs 83%, eosinophils 3%. Penicillin, 30,000 units three-hourly, was begun. No improvement occurred during the next week, and the patient was transferred to the Staffordshire General Infirmary on Sept 26. A diagnosis of dermatomyositis still seemed the most probable one, but the outlook appeared hopeless. A piece of muscle was excised from a tender oedematous site in the right adductor longus on Sept 29 to exclude the possibility of trichiniasis or polyarteritis nodosa. Half of this piece was kept for histology and half was placed into broth and incubated. By Oct 2 this culture yielded a pure and heavy growth of *Streptococcus viridans*. Two further blood cultures and culture of oedema fluid from the leg were sterile. Leucocyte counts were as follows during the illness.

Date	Total Leucocytes per cmm	Polymorphs %	Lympho- cytes %	Monocytes %	Eosinophils %
1/10/47	63 600	89	8	3	
3/10/47	59 800	86	11	3	
7/10/47	43 600	83	10	6	
13/10/47	15 600	78	17	3	
27/10/47	15 600	46	51	3	

In spite of this intense leucocytosis there was no evidence of suppuration at any time. Through an unfortunate laboratory error the sensitivity of the *Str. viridans* to penicillin was not determined, but the penicillin dosage was increased to 80,000 units three-hourly on Oct 3, and sulphadiazine, 1 g four-hourly was also begun. The sulphadiazine was stopped on Oct 14 after a total of 70 g had been given, and the penicillin was stopped on Oct 18 after a total of 8,120,000 units. "Benadryl" in doses of 200 mg daily had been given for four days from Oct 2, but without visible effect on the skin lesions or oedema. The skin lesions and oedema began to diminish on Oct 13 and the temperature had become normal by Oct 23. Electrocardiograms on Oct 3 and Nov 4 showed no abnormality apart from low voltage. The urine showed no abnormality throughout the illness apart from a trace of albumin. The patient returned home on Nov 16. The muscle-wasting was more pronounced than in the previous attack, but there has since been a rapid recovery.

Dr A J McCall has kindly given the following report on the sections of excised muscle: "The muscle shows numerous inflammatory lesions in which the muscle fibres are separated by collections of histiocytes and lymphocytes, with only occasional eosinophils and polymorphs (Figs 1 and 2). In some of these areas there is albuminous coagulum but frequently

there is none. The lesions are often perivascular, and they then tend to be spindle shaped. One or two small arteries show what is probably oedema of the vessel wall, with occasional inflammatory cells in the outer media, but there is no necrosis or thrombosis. Some muscle fibres appear normal, but others show damage varying from oedema to complete destruction and replacement by granular eosinophil material. Proliferation of sarcolemmal nuclei is sometimes seen. The frequency of the lesions varied considerably in sections taken from different levels in the block, and it is evident that they are patchy in distribution. No parasites or organisms could be found in any of the sections."

### Discussion

The clinical manifestations of acute dermatomyositis have been well recognized for more than sixty years, but although these are suggestive of a fulminating bacterial infection it is remarkable that an organism has been isolated on so few occasions. The isolation of a possibly causative organism in this case is so unusual that it must be examined with some scepticism.

It seems improbable that the *Str viridans* was an accidental contaminant of the culture, but lesions of the severity described are by no means a characteristic of *viridans* infections. They are never seen, for instance, in bacterial endocarditis due to this organism, even when a considerable degree of septicaemia is present. There was no evidence of cerebral, renal, or pulmonary lesions, which would be expected in a fulminating bacterial infection with such an intense leucocytosis. The localization of the lesions to the muscles and skin is the most remarkable feature of the case.

The similarity of the clinical picture to that of acute disseminated lupus erythematosus (Libman-Sachs syndrome), acute erythema multiforme of the Stevens-Johnson type, and polyarteritis nodosa has been mentioned, and it is possible that they also have a similar aetiology. In the past these diseases have been thought to be due to bacterial infection, but most authorities now regard them as manifestations of allergic hypersensitivity, in some cases to bacterial antigens. Ophuls (1923) first suggested that poly-

arteritis nodosa might be due to allergic sensitivity to streptococci, and Rich (1946) now emphasizes that substances of widely differing chemical nature must be added to the list of sensitizing antigens capable of producing vascular lesions. This conception of allergic hypersensitivity has also been applied to the Stevens-Johnson syndrome (Sutton and Sutton, 1939, quoted by Nellen, 1947) and to the Libman-Sachs syndrome (Fox, 1943).

Banks (1941) first discussed the question of whether there is a common denominator between scleroderma, dermatomyositis, acute lupus erythematosus, and poly-

FIG 2—Showing perivascular infiltration and slight inflammatory reaction in outer coats of small artery ( $\times 250$ )

arteritis nodosa. He draws attention to the overlapping of the morbid anatomical features in all these conditions, particularly of the arteriolar changes. The very slight histological evidence of vascular damage in this case is an inconclusive finding, but the severe recurrent symptoms localized to muscles and skin and the slow response to penicillin and sulphadiazine could be explained by the assumption that the disease was due to an allergic response to the *Str viridans*.

### Summary

Two severe attacks of dermatomyositis in a boy aged 15 are described. After many unsuccessful attempts to grow an organism from the blood and oedema fluid *Str viridans* was obtained in pure culture from a muscle biopsy during the second attack.

A piece of excised muscle showed patchy inflammatory changes with perivascular cellular infiltration and necrosis of muscle fibres in some places. Only slight infiltration of arterial walls was seen in the sections examined.

Complete recovery from both attacks occurred. In the first there was a slow response to penicillin alone, and in the second a slower response to larger doses of penicillin and sulphadiazine.

It is suggested that the severe symptoms were due to an allergic reaction in muscles and skin to the *Str viridans* infection and that a clinical and possibly an aetiological similarity exists between dermatomyositis, polyarteritis nodosa, acute disseminated lupus erythematosus, and erythema multiforme of the "Stevens-Johnson" type.

## POST-PRANDIAL SYMPTOMS FOLLOWING PARTIAL GASTRECTOMY

BY

W T IRVINE, B Sc, M B, Ch B

Resident Surgical Officer Warrington General Hospital

While the results following subtotal gastrectomy for ulcer are generally excellent, in a small proportion of cases there develop post-prandial symptoms which may persist for many months. Such post-prandial upsets after gastrectomy have been described in British, German, and American literature, and frequent attempts have been made to relate these symptoms to changes in sugar levels in the blood. Lawrence (1936) noticed that after such surgical procedures patients developed hyperglycaemic then hypoglycaemic sugar levels following ingestion of glucose. Evensen (1942) found that 34 out of 95 cases treated by partial gastrectomy developed unusually low blood-sugar levels after meals. Adlersberg and Hammerschlag (1947) divided such upsets into two groups—early and late. The early symptoms (sense of pressure and fullness in the epigastrium) they attributed to the rapid emptying from the stomach remnant. Later symptoms (palpitations, headache, dizziness, and perspiration) they believed to be due to chemical factors, especially hypoglycaemia. Gilbert and Dunlop (1947) believed the symptoms were due to hypoglycaemia, and they found that ephedrine administration lessened the upset. They suggested that the development of insulin sensitivity was a causal factor.

### Present Investigation

Twenty-four cases were studied—23 men and one woman. All had had subtotal gastrectomy for duodenal or simple gastric ulcer. The type of operation performed in every case was a gastrectomy, removing three-quarters of the stomach and the first inch of the duodenum, with an antecolic anastomosis. No valve mechanism was formed.

**The Nature of the Symptoms**—In mild cases (the majority) the patients complain of a heaviness and fullness in the epigastrium, accompanied by a curious sense of muscular or body fatigue, and want to sit down, in more severe cases they may have to lie down and may fall asleep. A flushing of the skin may occur and the patient often "feels hot" and may actively perspire. Giddiness and palpitations often occur. Such symptoms were present in all 24 cases. To this list of symptoms must be added bilious vomiting, which occurred in two of the cases. These two patients had all the other symptoms, but in addition after meals they felt very upset and wanted to vomit. They usually vomited about 30 to 45 minutes after meals, and thereafter felt very well and were able to go about their business. The vomited material consisted either of food heavily bile-stained or, as often, of 1½ pints (0.85 litre) of unmixed pure bile.

**Time Interval between Operation and Symptoms**—In every case the symptoms started either while the patient was in hospital or as soon as he went home and began to

live a normal life. In no case was there a time interval of some weeks, such as has been described by those who believe the condition to be due to the development of insulin sensitivity.

**Time of Onset of Symptoms in Relation to Meals**—In each case the symptoms started almost immediately after meals or, indeed, while the patient was still eating. The upset usually lasted 20 to 30 minutes. The rapidity of onset suggested a mechanical causation, and in nearly every case the symptoms could be brought on rapidly by eating more quickly, and by giving a larger meal the symptoms usually increased in severity. In no case did a group of late symptoms appear 1 to 1½ hours after meals.

### Type of Meal which Caused the Symptoms

In all 24 cases a careful study was made of the type of food and the amount taken at each meal in the day, and a rough measure of the total bulk of each meal and its total carbohydrate content was made. In 23 cases the symptoms appeared only after "the big meal"—i.e., the most bulky meal of the day. In almost all of these cases the carbohydrate content of "the big meal" was considerably less than the carbohydrate content of another meal in the same day which produced no symptoms. Indeed, the patients themselves in most cases clearly realized that it was the bulkiness of the meal which troubled them, and many noted that by missing the soup one day, and doing without pudding the next, they could avoid such symptoms altogether. In other words, the incidence of symptoms depended on the total amount of food eaten and not on its carbohydrate content.

In order to clarify still further the question whether the symptoms were due to bulk or to carbohydrate content each patient was given 50 g of glucose in water and the severity of the symptoms and their time of onset, etc., were recorded, the blood-sugar levels were estimated by MacLean's method. On the following day the patient was given a bulk meal containing scarcely any carbohydrate (about 6 g) and the severity and time of symptoms were again recorded. The blood-sugar levels were again estimated to check the fact that there was no rise in the blood sugar. In 16 of the 24 cases the symptoms were more pronounced after this bulk meal than they were after the ingestion of 50 g of glucose in water. In four cases the severity of the upset was equal, and in four cases the 50 g of glucose caused more upset than the bulk meal. In short, it was again shown that it was the bulk and not the carbohydrate content of the meal which mattered. It is, however, interesting to note that after these bulk meals the blood-sugar level rose to a moderate extent in most cases. Indeed, blood-sugar levels were recorded which were higher than one would expect after a meal of such small carbohydrate content. It will be suggested that this may be due to stimulation of the sympathetic system caused by distension of the gut, bringing about an adrenaline effect.

### Relation of Symptoms to Blood-sugar Level

It has already been stated that each patient had blood-sugar estimations done after the ingestion of 50 g of glucose in water, and the time during which the symptoms were present was carefully noted. The results are shown in the accompanying Table. By graphing the blood-sugar levels and marking on the graph the period of upset the following points were noted.

The symptoms appeared long before the sugar level in the blood had reached its peak. The symptoms were usually over before the blood-sugar level started to fall or before it fell below normal limits. In short, the symptoms appeared during the period of hyperglycaemia and the symptoms had

Blood-Sugar Levels after 50 g. of Glucose by Mouth

24	80	109	127	158	194	69	105	98	86

passed off before low levels of blood sugar were recorded. Furthermore, exactly the same symptoms were produced, often of greater intensity, with the bulk meals, where the blood-sugar levels showed a less marked rise and fall. An illustrative case, with typical blood-sugar curves, is noted below.

A man, aged 40, had a subtotal gastrectomy for duodenal ulcer 18 months ago. Since operation he has been complaining of fullness in the epigastrium for 20 minutes after meals with weakness and sweating. Palpitations are common and giddiness is often present. This comes on after his dinner at midday, which usually consists of soup, then fish or meat. If he takes any pudding of any sort, his symptoms are much worse.

Curve A shows blood sugar levels after 50 g. of glucose by mouth. Symptoms were slight. Curve B shows blood sugar levels after a bulk meal with almost no carbohydrate. Symptoms were pronounced after this meal. The period of symptoms is shaded. During this period blood sugar estimations were made every five minutes.

### Discussion

Post-prandial symptoms following partial gastrectomy are not likely to be due to hypoglycaemia. In all 24 cases they occurred in the hyperglycaemic stage. The symptoms were quite often over before the sugar level stopped rising. Even when hypoglycaemic curves were produced the symptoms did not coincide with that period, and a similar set of symptoms of at least equal intensity could be produced in the same patient with a bulk meal with a much smaller rise and fall in the sugar levels in the blood.

That these symptoms are due to mechanical distension of the gut is suggested by the following facts: (a) The rapidity

of onset of symptoms following the meal suggests a mechanical cause. (b) It was the major meal of the day which gave the trouble in 23 cases, and patients usually knew that they could avoid or lessen the upset by taking fewer courses. As has been said, this major meal in most cases had a smaller carbohydrate content than at least one other meal of the day which produced no symptoms. (c) In two-thirds of the cases the bulky low-carbohydrate meal produced more symptomatic upset, with only a moderate change in blood-sugar level, than did the 50 g. of glucose which caused a marked rise and fall in the sugar levels. Further, the very fact that the symptoms were the same in both cases suggests a mechanical basis.

It should be added that in the four cases in which the 50 g. of glucose caused more upset than the bulk meals no satisfactory explanation was found. These patients had no marked hypoglycaemia, and again the symptoms occurred in the hyperglycaemic stage. These four patients had insulin-sensitivity tests carried out. No hypersensitivity was found.

If the post-prandial upset is due to mechanical distension of the gut it is likely that the afferent pathway for this is in the sympathetic-nerve fibres and not the vagi. This is suggested by the work of Andrus (1947), who performed a preliminary gastrectomy on a patient with carcinoma of the oesophagus. At a later operation he did a bilateral vagotomy. By passing a cystoscope through the gastrectomy tube he was able to test the stomach wall for different types of sensation before and after vagotomy. He observed that most sensations, such as feelings of distension, heat and cold, pain, etc., were unaffected by vagotomy. Moore *et al* (1947) also observed such post-prandial symptoms following vagotomy.

Finally, the symptoms themselves suggest stimulation of the sympathetic system. The weakness, giddiness, perspiration, etc., are not unlike the effects produced by adrenaline and ephedrine. In this respect it is interesting to note that the pulse rate increased by 10 to 20 beats a minute in all 24 cases during the upset. Furthermore, the rise in the blood-sugar level after a meal containing very little carbohydrate might be explained by an adrenaline effect following stimulation of the sympathetic nerve by mechanical distension of the gut.

I would like to thank Professor Illingworth for his kind help and encouragement and for his many useful criticisms.

In Circular 150/48 (dated Aug. 20, 1948) the Ministry of Health has given some advice to County and County Borough Councils about their functions under the National Assistance Act, 1948. There are not to be any changes in the system of registration of blind persons or of the arrangements under which the Regional Associations for the Welfare of the Blind maintain regional registers. The certification of blindness will be part of the local authority's duty under the National Assistance Act and not under the National Health Service Act, and the Form BD 8 will continue to be used. Local authorities are to pay the regional boards for certificates provided by specialists employed by the board, but where the specialist does the work outside his employment by the board the local authority will pay him direct. In addition to persons registered as blind within the meaning of Section 64 of the National Assistance Act, local authorities are now urged to keep an "observation register" of those who are substantially and permanently handicapped by defective vision ("partially sighted persons"). Local authorities should keep these patients under review and make sure that they are obtaining the treatment they may need through the National Health Service.

## PUERPERAL SEPTICAEMIA DUE TO *PS. PYOCYANEA*: FAILURE WITH STREPTOMYCIN

BY

H SOBHI, M.B., Ch B., F.R.C.S., D.G.O.

AND

OMAR KHAIRAT, Ph.D., M.B., Ch B., D.T.M.&amp;H.

(From the Faculty of Medicine Farouk I University  
Alexandria Egypt)

Infections of the urinary tract with *Pseudomonas pyocyanea* have in many instances been successfully treated with streptomycin (Alexander, 1946, Hamre *et al.*, 1946, Keefer *et al.*, 1946). In the case described below, in which both the blood and the urine were infected with the organism, the patient died despite the sterilization of the blood and the urine with this chemotherapeutic agent.

### Case Report

A female aged 28 was admitted to the Farouk I University Hospital on Jan 26, 1947, complaining of excessive bleeding from the vagina for 28 days and backache. She was syphilitic, and had had an early abortion five months before admission, with amenorrhoea two months before the onset of her illness. She gave a history of recurrent attacks of salpingitis for seven years, for which she had had 60 administrations of short-wave therapy. Severe aplastic anaemia with marked leucopenia and gingivitis persisted till death—after 36 days in hospital. Blood examination: Hb 40% (Sahli), R.B.C. 2,000,000 per cmm, leucocytes 1,000 per cmm (polymorphs, 20%, lymphocytes 72%, monocytes 8%), platelets 13,000 per cmm, bleeding time, nine minutes, coagulation time, one minute. The urine contained a trace of albumin and a few hyaline casts. A Friedman test three days after admission was negative.

A low grade pyrexia developed the day after admission, but the temperature became normal after five days' treatment with a total of 20 g sulphadiazine orally and remained normal for four days. It then rose, and penicillin 5,000,000 units was given intramuscularly over 17 days. This had no effect on the pyrexia. Penicillin was stopped when a blood culture yielded *Ps. pyocyanea* and streptomycin, 1 g per day, was given intramuscularly every three hours until death seven days later. Penicillin was resorted to in addition to the streptomycin the day before death because the patient was thought to have developed pneumonia. The temperature remained high until death.

Bimanually the uterus was felt to be retroverted and retroflexed and could not be corrected on account of tenderness and probable adhesions. It was rather enlarged. The os was closed and the lower segment slightly softened. On the right of the uterus a tender mass the size of a hen's egg was felt, with pulsating vessels on it.

Four days after admission the os was dilated one and a half finger-breadths; the uterine cavity was filled with blood clots, but no products of gestation were found. The patient had probably aborted the day before. There were signs of moderate localized pelvic peritonitis.

The severe anaemia was treated with iron, liver extract intramuscularly, and blood transfusion—11 litres (194 pints) of blood. For the marked leucopenia which was accompanied by gingivitis (? agranulocytosis), the patient took pyridoxin every other day.

### Bacteriological Examinations

The first blood culture, made 11 days before death while the patient was on penicillin, yielded *Ps. pyocyanea* five colonies per ml of blood. When the result was known blood cultures (eight) were made daily until death. The first showed no signs of growth (turbidity) before 48 hours. Surface pellicle developed in both the aerobic and the CO<sub>2</sub> tubes. The top centimetre in the CO<sub>2</sub> tube was tinged pale green. No pigment developed in

the aerobic tube. This phenomenon was observed in all subsequent positive blood cultures. Carbon dioxide seems to enhance pigment production (Khairat, 1940).

*Ps. pyocyanea* was grown from the first three blood cultures, the last two gave one colony per ml of blood. The blood became sterile the third day after streptomycin had been started. *Bact. coli* was grown from the eighth (and last) blood culture, taken the day before death—presumably an ante-mortem invasion (*Bact. coli* was grown in pure culture from the heart blood two hours after death).

The patient's serum taken a week before death agglutinated a living suspension of the first blood culture strain (washed off an agar slope) to a titre 1:320. A suspension killed by heat (60° C for 30 mins) failed to agglutinate even in low serum dilutions (Final serum dilutions from 1:5 to 1:1,280 were put up). Agglutination of the living suspension took place at 55° C (water bath) after 18 but not four hours.

A throat swab taken six days before death was negative for *Ps. pyocyanea* and negative also for haemolytic streptococci. A *pyocyanea* bacillus was grown from the stools in small numbers seven days before death. Four urine cultures, taken aseptically by catheter, were made every other day the week before death. The first, taken the day streptomycin was started, yielded *Ps. pyocyanea* eight colonies per loopful of the thoroughly shaken urine and also *Bact. coli* six colonies per loopful (on blood agar, the loopful was approximately 1/150 ml). The two urine cultures which followed were sterile, probably because of the streptomycin. From the last urine culture, taken the day before death, both organisms were grown. *Ps. pyocyanea* and *Bact. coli* in equal numbers were grown from three cultures from the cervix uteri taken 7, 5, and 2 days before death.

### Necropsy

The uterus was retroverted and surrounded by fibrous adhesions that fixed it. It was almost completely involuted. On the right side there was a tubo-ovarian mass. The right ovary was cystic and contained thick sanguinous fluid. The small intestines showed septicaemic petechiae along the whole mucosa. The lower part of the ileum close to the ileo-caecal junction was markedly congested and almost gangrenous in appearance, but the loop was free in the abdomen and had no adhesions. (The patient passed no motions for four days before death.) The heart valves were free. The pericardium contained much straw-coloured clear fluid.

Post-mortem cultures were made two hours after death from the heart blood, pericardial fluid, cut-surface of lung, cervix, uterine cavity and from the thick sanguinous fluid in the cystic right ovary. *Bact. coli* was obtained in pure culture from all these sites, the pericardial fluid and the cut surface of the lung also yielded *Ps. pyocyanea*. The three blood culture *pyocyanea* strains, the three cervical ones, the strains from the stools and the urine, and the two post-mortem strains were all agglutinated to the same titre (1:320) by the patient's serum. Pooled normal human sera did not agglutinate any of them.

### Summary

Penicillin had no effect on *Ps. pyocyanea* bacteraemia or bacilluria. Streptomycin, 1 g daily, sterilized the blood and the urine by the third day, but did not save the patient, who died probably of paralytic ileus or from agranulocytosis.

We wish to thank Prof. Aly Bey Hassan for the gift of streptomycin and for his interest.

The National Under Fourteens' Council has issued an illustrated pamphlet entitled "Junk Playgrounds" describing how bombed sites and other derelict places may be made into suitable playgrounds for children to give them the opportunity of making small huts or gardens. This scheme has been very successful in Copenhagen, where it is claimed that juvenile delinquency has been eradicated by such measures. The Council is appealing for funds, and those interested should write to the Organizing Secretary at the Mary Ward Settlement, Tavistock Place, London, W.C.1.

## LAURENCE-MOON-BIEDL SYNDROME

BY

GRAHAM H ANDERSON, MB, Ch B, FRFSPS

The association of retinitis pigmentosa with polydactylism was recorded in 1860 by Laurence and Moon and the Frohlich syndrome in 1901. Biedl in 1921 described the pentad of polydactylism, obesity, hypogenitalia, retinitis pigmentosa, and mental retardation, with a familial occurrence, the association being now known as the Laurence-Moon-Biedl syndrome. Variants have also been described by Biesmond, Van Bogaert, and by Delhay in which coloboma of the iris replaced the retinal degeneration. Graefe in 1866 described optic atrophy as complicating oxycephaly, but not of the pigmentary degenerative type (Duke-Elder, 1940, Ridley and Sorsby, 1940). Mann (1937), however, records oxycephaly as one of the skeletal abnormalities which may be present with the syndrome.

Retinitis pigmentosa occurs much more often as an isolated disability than in combination with other disabilities. Nettleship worked out many pedigrees in which there was no other defect. Usher obtained similar results when searching especially for combined defects. In the Eugenics Laboratory Memoirs (1922) is reported a series of 914 cases, in 656 of which the patients suffered from retinitis pigmentosa alone. Deaf-mutism, or mental deficiency, occurred in 96 cases (10.41%), and was the commonest associated affliction. In only 9 cases (less than 1%) was polydactylism noted, such a combination is therefore rare. The genealogical tables constructed showed that retinitis pigmentosa could apparently be transmitted as an inherited Mendelian dominant, or recessive, or sex-linked character, whereas the Laurence-Moon-Biedl syndrome occurred as a recessive Mendelian type (Eugenics Laboratory Memoirs, 1922).

Pathological evidence of pituitary abnormality has generally been indefinite and disappointing. Dax (1938), however, reported the presence in the blood and urine, but not in the cerebrospinal fluid, of a substance which was melanophore-expanding in frogs and caused a visible darkening of the skin on injection. This substance could be demonstrated in cases of retinitis pigmentosa, with or without other abnormalities. It was also present in conditions of known pituitary stress, such as pituitary tumours, hyperthyroidism, and pregnancy. Similarly prepared extracts from healthy controls or other endocrinal upsets did not contain this substance. The presumption of a hypophysial-diencephalic lesion has thereby gained some experimental justification, but vascular phenomena, according to earlier Italian workers, also play an important part in the pigmentary degenerative process (Dax, 1938).

## Case Report

A spinster, aged 45, was admitted to ward 2 of the Western Infirmary, Glasgow, complaining of severe headaches occurring at frequent intervals over a period of two years. At birth rudimentary sixth digits were present on each extremity, but these spontaneously wasted and disappeared during her infancy. Soon after attending school she discovered her eyesight was defective, the defect being more pronounced at night. Ophthalmological examination at this time led to a diagnosis of retinitis pigmentosa. She had always been a fat child but less than average in height, and at the age of 11 she weighed 13 st (82.5 kg). Menstruation began when she was 13, a regular 4/28-day cycle continuing up to the time of writing.

Eczema first appeared at the age of three months and asthmatic attacks when she was four years old. Both have occurred intermittently throughout her life. Two years before admission she began to suffer from headaches, usually present

on waking but sometimes developing later in the day. The occipital region was generally affected, with occasional spread over the vertex and forwards to the frontal area. They were not accompanied by nausea, vomiting or any increased visual disturbance, nor were they induced by those foods which she had learned by experience to regard as provoking attacks of eczema or asthma.

On examination the patient was seen to be obese, but not grossly so. Her face was florid, with marked hirsutism but no congested veins. Her skin was dry and scaly, with one small weeping area on the dorsum of the hand. Small scars were present at the lateral bases of the fifth digits. Her skull was of a pronounced oxycephalic shape. Her weight was 12 st 11 lb (81.2 kg), her height 5 ft 4½ in (1.64 m).

Clinical and x-ray examination of the lungs was compatible with the asthmatic history. The blood pressure was 175/105 mm Hg. Clinical and special methods of examination revealed no other abnormalities in the cardiovascular system. Blood examination showed Hb, 75% (Sahli), red cells, 3,800,000 per cmm, white cells, 6,800 per cmm, films—normal cell pattern, normal sugar-tolerance curve—fasting, 0.100%, half hour, 0.170%, 1 hour 0.180%, 1½ hours, 0.100%, 2 hours, 0.090%. No sugar in the urine, nor was any chemical or microscopical abnormality detected. Average daily volume was 49 oz (1.39 litres). Average daily excretion of 17-ketosteroids was 3.7 mg (average normal, 13 mg with limits 4–23 mg, Hadfield and Garrod, 1947). The BMR was -19.5%. Examination of the CSF showed pressure, normal, cells, 2 per cmm, Wassermann reaction and colloidal gold tests (Lange), negative, no precipitation to Pandey's or Nonne-Apel't tests. Hearing was normal with both ears. Sight large objects seen at 6 ft (1.83 m) but without definition, individuals not recognized close up, strong contrast colours distinguished close up. Fundi peculiar degeneration and pigmentary deposits of retinitis pigmentosa. No papilloedema or changes in vessels. Radiographs revealed that the pituitary fossa was smaller than usual, that there was no bony abnormality, that the middle phalanges of both fifth fingers were "dumpy," and that there were rudimentary accessory digits at both fifth toes.

**Intellect**—The patient was alert and quickly recognized voices. Her interests were limited, but this was clearly the result of her defective vision and not due to any mental defect. Her knowledge and understanding of everyday events, as reported on the radio, was quite up to normal standards.

She could not trace back any relative with blindness or polydactylism. There has been no Jewish racial mixing in the family so far as she is aware. No abnormality was found on examination of her mother and sister, the only relatives available.

## Discussion

The above case is incomplete in two respects. Mental retardation was not an obvious feature, and amenorrhoea, which would be anticipated with hypogenitalism, was not present, an average normal menstrual cycle occurring during the patient's stay in hospital. The hirsutism was limited to the face and did not encroach on the male distribution of trunk and arms. The possibility of virilism (adreno-genital or pituitary basophilism) is further negated by the low excretion rate of urinary androgenic (ketosteroid) substances. Such low values are obtained in hypopituitarism.

A benign myxoedematous state, induced by inadequate stimulation of the pituitary to the thyroid gland, readily affords an explanation of the lowered metabolic rate and anaemia. Hypertension is not uncommon in myxoedema, and the headaches symptomatically conform to the pattern associated with increased blood pressure. I have not traced an association with eczema and asthma in previous cases, thus an unlucky coincidence seems to have occurred in this patient's case.

The failure to elicit a family history is not surprising in a Mendelian recessive type, as several generations may elapse in human inheritance before suitable conditions (absence of a neutralizing dominant or other less easily explained factor) occur. An isolated case cannot therefore

be assumed, but only that previous members of the family showing this syndrome have been buried even beyond the knowledge and memory of those still alive. Sufferers from this syndrome are of course unlikely to marry, and even if they do so are unlikely to have children—a factor which of itself curtails the passing on of the defective gene except as a latent recessive type.

My thanks are due to Dr D K Adams for permission to publish this report.

## Medical Memoranda

### A Fatal Case of Solanine Poisoning

Of the *Solanaceae* *A. belladonna* (deadly nightshade) has long been recognized as having very poisonous properties owing to the high content of atropine in the plant. The commoner members of the nightshade genus—*S. dulcamara* (woody nightshade) and *S. nigrum* (black nightshade)—are generally regarded as being harmless, although the alkaloid solanine has been recovered from the berries of these plants and has been shown to have toxic properties in experimental animals and to a less extent in human beings. We can trace only one authenticated case of death following ingestion of the red berries of the woody nightshade and one fatal case of black nightshade poisoning (Taylor, 1875).

## CASE RECORD

A female child aged 9 years was admitted to hospital on the evening of Aug 13, 1948, suffering from vomiting, abdominal pain, and distressed breathing. Her home was on the outskirts of a town and she was apparently in the habit of eating berries from hedges and from the embankment of a disused railway near her home. She had eaten berries on several occasions during recent weeks, the last occasion being three days before admission. The following day she had felt unwell but had improved. On the day before admission she had been taken ill with vomiting and had vomited "coffee-ground" material four times during the five hours before admission.

The child responded weakly to questioning and complained only of abdominal pain and thirst. She looked exhausted, the skin was pallid and dry, the expression anxious. There were slight restless movements of arms and head. She was not delirious. A feature which remained marked throughout was dyspnoea. Inspiration was short and gasping, expiration was prolonged and active and accompanied by a sigh. The respiratory rate was 32 per minute.

The pupils were of normal size and reacted to light. Although the child was dehydrated the tongue was moist. Examination of chest and abdomen revealed nothing of significance. The extremities were warm. There was neither paraesthesia nor paralysis. Temperature 96.4° F (35.8° C), pulse rate 140 per minute, blood pressure 120/88.

A provisional diagnosis of vegetable irritant poisoning with central effect on the nervous system was made, and treatment was immediately instituted. This included stomach lavage, soap and water enemas, nikethamide 17 ml hourly, and latterly oxygen. Fluids were given by mouth and per rectum. Some improvement in her general condition was maintained for 24 hours, but she later became weaker and more cyanosed and her respirations became very feeble. Death occurred in the morning of Aug 15, 1948.

A post-mortem examination was carried out two hours after death. The main feature was an acute inflammation of the mucosa of the stomach and intestines, the inflammation decreasing in intensity towards the distal coils of small intestine and caecum. There were small haemorrhages in the mucosa of stomach and jejunum. The stomach contained about 1 pint (568 ml) of dark brown fluid and dark greenish brown semi-solid material was present in the upper coils of jejunum. The bowel contents decreased in amount and became paler towards the distal end of the small intestine. The contents of the colon were normal in appearance. Small fragments of the skin of a berry were found microscopically. The rectum was empty. Other abdominal organs appeared healthy. Thoracic organs, with the exception of the lungs, which were congested and oedematous, appeared healthy. The brain was normal in appearance.

Microscopically the liver showed moderate fatty infiltration and necrosis.

The post-mortem findings were regarded as being consistent with death from respiratory failure following the ingestion by mouth of some poisonous substance, and specimens of stomach and intestinal contents and liver were submitted for analysis. No alkaloid was found in the liver by the normal Stas Otto process. A special search was made for solanine, and from about one-third of the liver 7 mg of crude alkaloid was isolated, which on recrystallization from alcohol gave a product giving characteristic tests for the solanine complex.

A search at the place where the child played revealed the presence of masses of woody nightshade entangled with blackberries. The child's symptoms, the finding of solanine in this organ and the presence of much woody nightshade where the child played provide evidence that death was almost certainly due to poisoning by *Solanum dulcamara*.

## DISCUSSION

Fatal cases of solanine poisoning are very rare, and although much work has been done on the potato as a source of the poison very little appears in the literature concerning the other two common sources, *Solanum dulcamara* and *Solanum nigrum*. It is known that the potato varies greatly in solanine content with the season of growth. Abnormally wet summers appear to favour high alkaloidal content. It appears possible that *Solanum dulcamara* may be subject to similar variations and that this abnormally wet summer may have favoured high toxicity of the berries. Recorded cases suggest that some individuals may be abnormally sensitive to solanine.

According to Reil (1857) solanine destroys life by producing paralysis of the muscles of the chest. It is a slow acting poison, and so far as we know has not yet been isolated from the vomit or stomach washings of suspected cases. It differs from atropine (deadly nightshade) and hyoscyamus (henbane) in not producing stupor or delirium, dilatation of the pupils, sphincter paralysis, or pyrexia.

Plants of the genus *Solanum* can be identified only by a botanical examination of the leaves and berries. The following brief accounts are extracted from Bentham and Hooker (1945).

'(1) *Solanum dulcamara*. Synonyms Bittersweet, woody nightshade, felonwort, violet bloom, scarlet berry. Found commonly in hedges and thickets in moist shady situations all over Europe except the extreme north. Common in England and Ireland. Rare in Scotland. Stem shrubby at base, with climbing or straggling branches, often many feet in length. Leaves stalked, ovate or ovate-lanceolate, two or three inches long, usually broadly cordate at the base and entire, but sometimes with an additional lobe or segment on each side. Flowers rather small, purple or blue with yellow anthers, in loose cymes, on lateral peduncles shorter than the leaves. Flowers in summer. Berries small, globular or ovoid and red when mature.'

'(2) *Solanum nigrum*. Synonym black nightshade. One of the most widely spread weeds. Common in England but local in Scotland and Ireland. An erect annual or biennial with very spreading branches, about a foot high. In Britain usually glabrous. Leaves stalked, ovate with coarse angular teeth. Flowers small and white in little cymes almost contracted into umbels on short, lateral peduncles. Berries small, globular, black.'

### Five Cases of Belladonna Poisoning

On Sept 2, 1948, at 10.30 a.m., three children, Rosemary and Elizabeth, aged 7, and John, aged 8, were admitted to St Mary's Hospital, Portsmouth, with the statement that during the night they had become delirious, lost the use of their legs, and could not see. All three were extremely restless on admission, twisting about, plucking at the bedclothes, and constantly grimacing. John and Rosemary were extremely talkative and obviously hallucinated, their speech was a little slurred. Elizabeth appeared to have some photophobia and lay with her head buried in the pillow, fiercely resisting any interference. All three children had hot, dry skins and a marked malar flush. The lips were dry and fissured, the pupils widely dilated and inactive to light. They had rapid pulses, 120-130, but normal temperatures and respiratory rates. The highest B.P. recorded was John's, 138/80 mm Hg. Lying in bed there was no obvious muscular incoordination, though they continuously executed purposeless movements. All deep reflexes were brisk. The following facts were elicited from the mother.

The patients and another brother had gone out to play in the park the previous afternoon. They returned home about 5 p.m. stating

they were very tired and did not want tea, all complained of great thirst but otherwise appeared to be normal. At 7 p.m. the children went to bed and slept. At 9 p.m. three were awake and extremely restless. Their speech was rambling, they complained of being unable to see, and John, who climbed out of bed, "kept falling about the room." The mother thought all of them had high temperatures.

The fourth child in the family remained unaffected, and during the morning directed us to a plot of waste ground where there were two large blackberry bushes covered with ripe berries. Entwined among the stems were several plants of deadly nightshade (*Atropa belladonna*) also bearing large black berries. The child stated that he had eaten one berry, but five more children "had eaten a lot." Three of the five were the patients, and the fate of the other two was at this time unknown. Later during the morning the hospital was asked to admit a child, Keith, aged 9.

On arrival he was found to have a hot, dry skin, rapid pulse, and moderately dilated pupils inactive to light. He was extremely drowsy and resentful of any examination. The story was that this child had been blackberrying with the others. He had a large tea at 6 p.m. and went to bed at 9 p.m., apparently a normal child. At 2.30 a.m. the morning he was found fighting with his elder brother. He talked incoherently, did not appear to know his parents, and kept picking imaginary objects off the bedclothes. At 4 a.m. he was given morphine by a local doctor, and remained drowsy up to his admission at 1.30 p.m.

Just after his arrival a fifth child, Derek, aged 6, was admitted with identical symptoms to the first three. He had returned from the blackberrying party about 7.30 p.m., had his supper, and went to bed. He was awake and vomited twice during the night. At 6.30 a.m. both parents went out, leaving the child in charge of an elder sister. The sister sought the help of neighbours about 12.30 p.m. because the boy was talking strangely. The onset of symptoms in this case must have been delayed for twelve to eighteen hours.

#### TREATMENT

On admission gastric lavage was carried out on all five children, first with plain water then with potassium permanganate solution, 10 gr (0.65 g) to the pint (568 ml). This procedure induced vomiting, and over 30 berries were recovered from John's stomach and nearly as many from his two sisters. The berries, mixed with gastric contents, closely resembled raisins, but the seeds were smaller and darker than raisin 'stones'. No berries were recovered from Keith and Derek.

Rectal wash-outs with normal saline were also given, but no seeds or berries could be detected in the washings. Four hours later the gastric lavage was repeated, and several more berries were obtained from John and one of his sisters. At the end of the lavage a solution containing magnesium sulphate 90 gr (6 g) was left in the stomach.

By late evening there was no appreciable change in the children's condition, all were still extremely restless and hallucinated, pulse rates remained high, and they were all incontinent. At no time was there any evidence of urinary retention. During the night they slept sporadically, and by 9.30 a.m. the next morning all, except John, were quieter and fairly co-operative, though suspicious and resentful of any examination. The children all complained of great thirst and two of severe frontal headaches, there was still a marked malar flush, but the pupils were smaller and showed a slight reaction to light. The saline aperient was repeated, and all had several bowel actions during the day, by evening large numbers of seeds and berry skins were still being passed by John and his two sisters. At a conservative estimate John must have eaten at least 40 berries, and his two sisters between 20 and 30. Why no berries or seeds should be recovered from the other children, whose symptoms were no less severe, is a mystery.

The important features in these five cases of poisoning appear to be: (1) The prolonged period between the ingestion of the berries and the appearance of symptoms. (2) The absence of any fever or respiratory depression and the prominence of the hallucination. (3) The significance of "raisins in the vomit"—so unlike fresh deadly nightshade berries—might not have been appreciated in a case where no history of eating berries was obtainable. (4) The necessity for administering an emetic: many of the berries would have blocked the largest size of stomach tube.

## Reviews

### MODERN OPHTHALMOLOGY

*Modern Trends in Ophthalmology* Edited by Arnold Sorsby  
Volume 2 (Pp 600, illustrated £3 3s, plus 1s 6d postage)  
London Butterworth and Co (Publishers) 1948

*Modern Trends* does not aspire to be a textbook describing its subject adequately and fully, but, like a connoisseur, surveys the whole field, neglects what is fully established and has become ensconced in the standard textbooks, and discusses those aspects of the subject which are showing emergent tendencies, in which active research is progressing, and which are still matters of speculative interest. A book of this kind, if written by those who are contributing actively to new knowledge and edited adequately and with wisdom, is of great interest. The first volume in this series appeared in 1940. The second, which is now published and contains accounts of many subjects not included in the first, maintains the same standard of excellence as its predecessor.

There are forty-eight articles on all aspects of ophthalmology—physiology, optics, diagnostic procedure, pathology, treatment, and social aspects—written by authors in Britain, the Continent, and the Americas. They are all of high standard and it would be invidious to single out any for special mention, although some of them are somewhat short and superficial. A composite compilation of this type often suffers from great inequalities but the thoroughness of the editorship is seen in the relative standard maintained in the presentation of the various sections: many of these must have been rewritten. The illustrations and the general production of the book are a credit to the publisher.

STEWART DUKE-ELDER

### THE DIFFICULT ADULT

*The Doctor and the Difficult Adult* By William Moodie, M.D.,  
F.R.C.P., D.P.M. (Pp 296 15s) London Cassell and Co  
1947

Dr Moodie, primarily a child psychiatrist, has always maintained that it is just as necessary, if not more so, to treat the parent as to treat the child. He has therefore provided a sequel to his book on the difficult child with one on the difficult adult and how the medical man may deal with such a problem. Throughout the book he is at pains to show how the difficult child becomes the father or mother of the difficult man or woman by handing on his peculiarities of idea, emotion, and behaviour, not by heredity but by example.

The book starts with a brief résumé of the progress of psychiatric understanding of mental illness during the present century, but the author deprecates the modern tendency to pamper the neurotic, whereby he may derive more advantage than ever from his illness and assume an importance in the family and the community which is not warranted. He warns against the possibility of the psychiatrist encroaching too far into the fields of education and criminology and making practical issues of half-digested theories. The descriptions of the psychoses and psychoneuroses are admirably terse, and the narratives of the illustrative cases are throughout so vivid and dramatically told that a living picture of the individual patient is presented to the reader. Dr Moodie makes a useful distinction between the anxiety neurotic, who thinks but really does not feel, and the agitated depressive, who feels intensely, often attributing his distress to a situation which is really the outcome of the depression. He points out that obsessive people live close to the unconscious and are closely allied to the schizophrenic, so he doubts whether they should be classed with the psychoneurotic.

He briefly discusses epilepsy emphasizing its close association with emotional disturbance and the harm that may be done both to the patient and his relatives by too ready diagnosis of a disease that they dread so much. In many cases simple psychotherapy may be very effective and a hopeless prognosis very

detrimental. In discussing mental and emotional defect he makes it clear that intelligence tests are all too easy to perform but all too difficult to interpret. Intelligence profiles are much more useful than the plain IQ. He gives a sound account of the approach to and general and special psychological treatment of patients and points out that really deep analysis is only seldom necessary. Full physical examination must never be neglected and physical treatments may be useful in saving the face of the hysteric, provided that the doctor, and probably the patient too, clearly realize what is being done. Dr Moodie is sceptical but not condemnatory of the modern physical treatments of the psychoses and is content to await further experience before passing a final judgment. The last chapter is on the milieu necessary to allow the mentally healthy child to grow into a mentally healthy adult, and the author refers particularly to child care in an affectionate and balanced home which is not disturbed by parent teacher or doctor.

This is just the sort of sound, well-balanced, informative book which anyone who knows Dr Moodie would expect from his pen, and all who read it—and there should be many—will not be disappointed.

## GYNAECOLOGICAL ANATOMY

*Gynaecological and Obstetrical Anatomy* By C F V Smout M D, M R C S. With Chapters on the Histology of the Female Reproductive Tract and its Endocrine Control, by F Jacoby, M D Ph D. Second edition (Pp 248, 185 figures many coloured £2) London Edward Arnold

The first edition of this book was deservedly popular, but the new edition, compiled with the help of Dr F Jacoby, who has written four chapters on the histology and physiology of the ovary and uterus, is a great improvement. The photomicrographs are of fairly good quality. The other illustrations are plentiful, though not quite up to the standard of the best modern publications. The book should be widely read by candidates presenting themselves for the higher examinations in gynaecology and obstetrics and there is clearly a big demand for a book of this kind.

Certain general criticisms can be offered. A fair amount of the subject matter is discussed in general textbooks and some of it should be omitted. On the whole the standard of the work is not sufficiently advanced for the senior students of to-day. Dr Smout describes the normal bony pelvis and the different types of contracted pelvis in some detail, and it is interesting to read the opinion of the pure anatomist on the different types of pelvic deformity which have been identified by x-ray examination. The account of the anatomy of the pelvic floor is not, perhaps sufficiently detailed. The original work of Tandler and Halban has withstood the test of time and should be mentioned, and more emphasis might be placed on the publications of Curtis and his co-workers. Further, the pelvic fascia is not divided into the pelvic fascia proper and the endopelvic fascia. Anreich's work is not mentioned.

The chapter on the histology of the ovary is good, but Dr Jacoby should have emphasized more the work of Brewer and of Rock and Hertig, although all these authors are mentioned. The description of the pituitary hormones is excellent, and the author has shown a fine selectivity in delving through the literature. There is the usual difficulty in locating the limit of the lower uterine segment in the non pregnant uterus, but he might have mentioned Aschoff's anatomical internal os and his histological internal os. Operating gynaecologists would possibly welcome an accurate description of the small arteries and venous plexuses found in the vicinity of the cervix and upper part of the vagina and perhaps Dr Smout might consider including one in the next edition. The aetiology of prolapse is well described, although there may be differences of opinion about the direct supports of the uterus—for example the practical-minded gynaecologist might object to the statement that the vagina, the broad ligaments and the round ligaments should be regarded as direct supports of the uterus. Markee's work is recognized, and we notice with interest that the authors pay sufficient attention to Rakoff's work on the biology and histology of the vagina.

WILFRED SHAW

## HUMAN FACTORS IN INDUSTRY

It is now coming to be understood that efficient production depends on industrial morale no less than on tools and equipment. Morale in industry depends in turn on mutual trust between manager and worker and on a sense of common responsibility and participation as much as on financial incentives. The re-equipment of industry necessary for increased output may take many years, but effects of great ultimate value, as well as more immediate results, may be obtained if a better use of human effort can be secured through an improvement in human relations in industry. In December, 1947, the Lord President of the Council set up a Panel on Human Factors, under the chairmanship of Sir George Schuster, as a permanent part of the Government's Committee on Industrial Productivity. This Committee advises the Government on the application of scientific knowledge in the present economic crisis and on the promotion of short-term research aimed at increasing output. The Panel's terms of reference<sup>1</sup> are "to advise the Committee regarding the directions in which productivity could be increased by the application of research into the human factors in industry and to make recommendations for further research in this field where called for." The British Medical Association appropriately invited Sir George Schuster to open a discussion on human relations in industry in the Section of Occupational Health at the Annual Meeting which was held in Cambridge last July, and his paper appears in the opening pages of this issue. In it he cogently presents one argument of importance to the medical profession. Industrial medical officers in different occupational groups can and should, through the intimate and individual nature of their vocation, have an important effect for good in the field of human relations. Medicine has already shown that it can contribute to the better deployment of human skill, there should therefore be an immediate and comprehensive expansion of occupational health supervision as part of the national plan for increasing productivity.

Sir George Schuster suggests that medicine can assist industrial productivity in three ways. The medical officer can attempt to fit the man to the job and the job to the man, he has the opportunities for sympathetic contacts with individuals, and he is in a position to plan and direct a positive health policy. But to fit the man to the job or the job to the man the profession must become more knowledgeable about work and working conditions than it is

at present. The doctor must be prepared to equip himself with a wide and intimate personal experience of industrial life. One immediate opportunity to do this comes through the study of disabled workers and the problems of their retraining and resettlement. Success in placing disabled men and women in suitable jobs through mutual co-operation means that relationships of the right sort are established. Industry, on the other hand, must pay more attention to the problem of fitting the job to the worker and also to its moral obligations towards him. Sir George Schuster and his Panel, in addition to planning new investigations, will no doubt consider how the results of past research can now be implemented in practice by managers. Some doctors may possess a deeper human understanding of individuals than others, but all need experience and training in how to link human understanding with the day-to-day realities of occupation and how to translate good will into action. The individual man at work offers a great scope for study with the purpose of providing detailed information about the meaning of individual differences and motives, and the basic importance of participation and satisfaction. Arising from this will come the need for a closer investigation of working groups, and for more knowledge of the intricacies of collective attitudes and of sources of discontent and unrest.

The necessity for making future managers aware of these issues is shown in a recent report of a committee set up by the Minister of Education<sup>2</sup>. Over 400,000 persons are "engaged in managerial functions" at present, and 12,000 recruits are required annually. For men already in jobs training is to be on a part-time basis, over one or two years. The proposed syllabus is ambitious, particularly where it covers the fields of occupational health and psychology, but evidently the scheme is now accepted by the Government. Thus the need to inculcate into industry the importance of the human factor and its relation to a positive health policy is obviously accepted in the highest quarters, and a great opportunity is therefore presented. It is imperative that industrial doctors, as well as managers, should receive further training in this same field, not necessarily in short, condensed courses, as has been the tendency, but spread over two to three years. Some scheme might be evolved for interchange of views and for pooling of experiences, perhaps by combined "schools" for managers and doctors. So far the medical faculties of our universities have shown little evidence of understanding how medicine might thus contribute to the national well-being. If the university departments of occupational health now being developed in various industrial areas are to be nationally effective they must give close attention to the need for postgraduate education in individual psychology and the practical application of studies in human relations in industry. If Sir George Schuster and his Panel agree with this proposal, a stimulating impetus, backed perhaps by the Treasury, might well be given to those responsible for postgraduate medical training.

Recently an encouraging account was published in *The Times* of the initial work of the Panel. It has set up a research advisory group with representatives of the Medical Research Council, the British Institute of Management, the

<sup>1</sup> *The Times* Aug 10 1948<sup>2</sup> *Education for Management* 1947 HMSO London<sup>3</sup> *British Medical Journal* Aug 28 p 436

Tavistock Institute of Human Relations, and the National Institute of Industrial Psychology. A programme of short-term research drawn up by this advisory group is now to be undertaken. The Medical Research Council has accepted responsibility for the administration of this work—with the exception of that undertaken by the British Institute of Management, which has its own sources of support—including administration of the necessary funds which will be provided specially by the Treasury for these investigations. The programme includes studies of productivity in certain Royal Ordnance factories, the design and measurement of human performance, the effects of ageing on industrial productivity, methods of joint consultation, intra-management relations, the status, selection, and training of foremen, and the effect on production of the size of the unit. Research will be carried out under the direct supervision of experienced workers from such places as the Cambridge Applied Psychology Unit of the M.R.C., the Nuffield Research Unit at Cambridge, and the Tavistock Institute of Human Relations. It has been, and still is, difficult to find the right field workers. There is a general lack of persons suitably versed in the social sciences, and few facilities appear to exist at present for training likely candidates.

A similar challenge to the medical profession has been made by another layman, Professor William Linc, a psychologist from Toronto. Speaking recently at the International Congress on Mental Hygiene<sup>2</sup> in London on ways and means of promoting "mental health" in industry—another name for the human factor—he insisted that doctors must take the leadership in research. He saw the potential advantage of their neutrality in management-worker relationships, and argued that high ethical standards have to be maintained, that training for doctors entering industry is vital, and that research into all matters of occupational health may have repercussions, possibly where least expected, of considerable importance in the field of human relations. In this last respect he wisely suggested that investigations into the health of the juvenile at his place of work should be undertaken immediately. He would no doubt agree that no close plan of always having a doctor as the leader could be effective; leadership in this connexion depends on opportunity, the nature of the problem, and individual qualities. In one place the chemist may be the pivot, in another the sociologist. Professor Linc is on more controversial ground, however, when he demands for the research worker an unqualified right to scrutinize the inside of industry. Such a demand, at least in so far as this country is concerned, must be qualified by appreciation of practical realities and difficulties. There are difficult problems here, and research, which is bound to be governed by the tempers and emotions of individual human beings, will be successful only when management at all levels and employees in all groups feel that they are themselves participating in the search for knowledge. The human factor in industry cannot be considered in isolation, nor can it be investigated on the laboratory floor. So it is more than ever important, if Sir George Schuster's research schemes are to materialize happily, that those taking part have a full appreciation of these fundamental issues.

## CONTROL OF DENTAL CARIES

A conference held last year at the University of Michigan was attended by dentists and others specially interested in the control of dental caries. In addition to hearing and discussing papers dealing with various aspects of the caries problem the delegates set up six evaluating committees to examine the literature and present reports embodying what seemed to them to be the most generally accepted present-day views. Had such a conference been held in this country a prominent place on the agenda would doubtless have been assigned to a discussion of the effect on the incidence of caries of dietary changes during recent years. It is perhaps not surprising that one finds no reference to this question in the report<sup>1</sup> of the American conference proceedings, but the paper by Lady Mellanby and Dr Helen Mellanby which was published in the *Journal* two weeks ago (p. 409) provides much valuable information on the subject. Previous reports<sup>2</sup> recorded the incidence of caries in the deciduous teeth of 5-year-old London children in 1929, 1943, and 1945, and this latest paper in the series brings the story up to 1947. Between 1943 and 1947 the proportion of children completely free from caries increased from 14.9 to 28.1%, and the percentage of deciduous teeth which were carious decreased from 30.1 to 20.3. The improvement in the period 1945-7 is shown to have been greater than in the period 1943-5, and the authors consider that this is due to the fact that "throughout the whole antenatal and post-natal life of the latest group of children examined, who were born between November, 1941, and October, 1942, the diet available has been of consistently better calcifying qualities than that of the subjects of the earlier surveys. The pre-eruptive diet has produced better-calcified teeth than were formerly observed, and the post-eruptive diet has tended still further to increase the already higher resistance of these teeth to caries."

While there was some support at the Michigan conference for the view that teeth are more susceptible to caries when formed during a period of deficient vitamin-D intake, the members of the evaluating committee to which this subject was assigned felt unable to consider it as established that the vitamin-D content of the post-eruptive diet has any influence on the prevention or retardation of dental caries. Even during the period 1945-7 the majority of the children examined by Mellanby and Mellanby were by no means free from caries, and they suggest, as a result of a small-scale inquiry which they carried out, that many mothers did not obtain all the special foods which they might have had. This could be confirmed by an inquiry on a larger scale, but the finding would be of little value unless an investigation were also made with the object of discovering whether or not the incidence of caries tends to be higher in those children whose mothers do not fully utilize the available supplements than in those whose

<sup>5</sup> Weaver R. *Brit. dent. J.* 1944, 76, 29.

<sup>6</sup> Weaver, R. *ibid.* 1944, 77, 185.

mothers do avail themselves of all the supplements to which they are entitled. It has been generally believed that the diet available for the population of the Channel Islands during the enemy occupation was much inferior to that in Great Britain, and yet Knowles<sup>3</sup> has recorded that in 1945 as many as 51% of the children aged 3-7 years remaining in the Islands had complete dentitions free from caries, while the figure for children of the same age group evacuated to this country was only 11%.

Dental hygienists have been widely employed in the USA for a good many years, and there is therefore special interest in the statement by one of the Michigan evaluating committees that there is no statistical evidence that prophylactic cleaning three or even more times a year will reduce the caries-attack rate. Some years ago Bibby<sup>4</sup> expressed the view that it was futile to try to control dental caries by prophylactic treatments of the conventional sort, and he suggested that advocacy by the dental profession of such treatments as a method of caries control was to be deprecated as something which would redound to the discredit of dentistry. Suggestions for legalizing the employment in this country of hygienists on the same lines as in America have alarmed some members of the dental profession, who see in this proposal a "weakening" of the Dentists Act, 1921, but such fears should not prevent amendment of the Act if the work of hygienists were of proved value. There are, however, other members of the profession who have always found it difficult to see how prophylactic cleaning, however thoroughly carried out, at intervals of some months could possibly influence the caries-attack rate. It should be noted that the Michigan statement refers only to reduction of caries incidence, it leaves it still open to the advocates of the employment of hygienists to claim that periodical prophylactic cleaning produces other results of value.

The subject which seems to have attracted more attention at Michigan than any other was the use of fluorides for the control of caries. The caries-inhibiting property of drinking water which naturally contains 1 part per million or thereabouts of fluorine is now established beyond dispute. It would be surprising if artificial fluorination of water to that extent failed to produce the same effect on caries incidence, but proof must await the outcome of the fluorination experiments which are now in progress in certain localities in the USA and Canada. Meantime enthusiasm in those countries for the topical application of fluoride solutions to the teeth seems to be increasing. There have been numerous reports in which it is claimed that three or four applications of sodium fluoride solution, usually in 2% strength, have reduced the incidence of caries by about 40%. There appears to be a reluctance on the part of the enthusiasts to consider whether their topical applications really prevent the development of caries or merely postpone its onset. Weaver<sup>5</sup> recorded the incidence of caries in the permanent teeth of 12-year-old children in South Shields as being only 56% of the corresponding figure for North Shields children, and he was eventually satisfied that the lower incidence in South Shields was due to fluoride in the drinking water. Further investigations,<sup>6</sup> however, led him to conclude that this apparently remark-

able reduction was not evidence of real prevention of caries but merely of postponement, and only for the relatively brief period of three to five years. It is possible that others who believe they can "prevent" caries might have to modify their views if they were to subject their findings to the same kind of examination as was applied to the South Shields figures. That examination showed that the incidence of caries in 15-year-old pupils in South Shields was approximately the same as the incidence in 12-year-old pupils in North Shields. Expressed in that form the findings may justify a moderate degree of satisfaction, but certainly not enthusiasm.

## ARTIFICIAL INSEMINATION

The commission on artificial human insemination appointed by the Archbishop of Canterbury has just issued its report.<sup>1</sup> A document sponsored by such authorities as Dr J W C Wand, the Bishop of London, Professor E O James, and Professor R C Mortimer for the Church, with Dr E A Bennet and Miss Louisa Martindale for medicine and Mr Justice Vaisey and Mr H U Willink, K C, for the law, is certain to command attention, and this is in fact a highly informative study of a very difficult subject.

All the members were agreed that when the procedure can properly be described as "assisted insemination"—that is, as a sequel to normal or attempted normal intercourse between husband and wife—it may be justified. With Professor Mortimer dissenting, the commission further found that when "assisted insemination" is inapplicable or ineffective other methods of using the husband's semen may be employed, even if there is no practicable alternative to masturbation. All the members except the Dean of St Paul's, Dr W R Matthews, were agreed that artificial insemination with donated semen (AID) brings about a breach of the marriage: it violates the exclusive union set up between husband and wife, defrauds the child begotten, and deceives both his putative kinsmen and society at large. For donor and recipient the sexual act loses its personal character and becomes a mere transaction. For the child there must always be the risk of disclosure, deliberate or unintended, of the circumstances of his conception. The commission, again excepting Dr Matthews, therefore judged AID to be wrong in principle and contrary to Christian standards. Moreover, following the advice of the legal members, who contributed a special section to the report and, incidentally, on the authority of Mr Justice Vaisey and the Rt Hon H U Willink, condemned the memorandum issued by the Medical Defence Union as "superficial and indeed grossly misleading," criticism to which Dr Robert Forbes replies elsewhere in this issue (p 530), a majority of the commission added that the evils involved in AID were so grave that early consideration should be given to the framing of legislation to make the practice a criminal offence.

This extreme condemnation reads somewhat incongruously in contrast with the impartiality, almost approaching sympathy, with which AID is handled in the body of the report. Such evidence as was available from practitioners who had used the technique was considerably in favour of AID in suitable cases, and the opposition, apart from that of the legal members, was almost entirely founded on conjecture.

<sup>1</sup> *Artificial Human Insemination* 1948. London: SPCK. Pp 70. 2s. 6d.

From this point of view the note contributed by Dr Matthews, the dissentient member, is especially interesting. While deferring to the legal opinion, he suggests that if AID is now contrary to law any further legislation may be unnecessary, and that a law imposing penalties would be difficult to enforce without the cordial co-operation of the whole medical profession, which might not be obtainable. He considers the commission to have been too eager to reach final and absolute judgments on a matter which is as yet imperfectly understood. He confesses repugnance to the whole idea of artificial insemination as tending to reduce life to mechanism and to degrade our conception of personality. Some of the conjectural ill-effects of AID seem to him, however, unlikely to occur, and he sees no reason to suppose that the psychological difficulties arising from it would be different from or more acute than those observed in adopted children. The real question in his view is whether AID can ever be morally justified, if it is to be condemned absolutely, it can on no conditions ever be right. He is not convinced by the theological argument, preferring to deduce moral laws from the Christian ethic of love rather than from a changeable theology or from a supposed law of nature. He also deprecates the adoption by Christian teachers of the "crassly materialistic" hypothesis on which the lawyers call AID adulterous when carried out at the request of the husband and with due precautions against injustice to others. The spiritual elements which constitute the sin of adultery are, he judges, absent. Without being in any way an advocate of AID, he has in fact stated the case for it about as strongly as it could be stated fairly in the present condition of our knowledge. Whichever of these two views the reader prefers, and whatever criticisms may be made of the conclusions of the majority of the commission, this report is bound to stand for a long time to come as an outstandingly able summary of this complicated question.

### POST-GASTRECTOMY SYNDROME

In a proportion of cases a syndrome of varying degrees of severity may follow partial gastrectomy, post-prandial symptoms of dizziness, palpitation, sweating, epigastric discomfort, and a feeling of extreme weakness progressing on occasions to complete loss of consciousness are the usual symptoms. They may appear thirty to sixty minutes after meals or may not appear for two to three hours. They have generally been attributed to hypoglycaemia following the rapid rise and fall in the blood sugar after the relatively undelayed passage of a carbohydrate meal into the small intestine. Barnes<sup>1</sup> reported three patients who, after gastrectomy, developed crippling symptoms of hypoglycaemia coming on two to three hours after meals. Gilbert and Dunlop<sup>2</sup> supported this theory, but in both the cases they record in detail the correlation of the symptoms with the fall in blood sugar was unconvincing, for the symptoms came on quite soon after meals. Adlersberg and Hammerschlag<sup>3</sup> suggest a way out of the difficulty by dividing the post-gastrectomy syndrome into two types. In the early type, which corresponds to the so-called "dumping" syndrome, the symptoms appear soon after a meal and are possibly due to mechanical factors, the small stomach emptying its contents rapidly into the small intestine. Small meals and lying down after them gave relief. The late type, coming on after several hours, was relieved by food and attributed to hypoglycaemia, which

followed the initial hyperglycaemia resulting from the rapid passage of carbohydrate into the intestine.

Elsewhere in this issue (p 514) Dr W T Irvine reports the results of his investigation of 24 patients who developed early post-prandial symptoms following partial gastrectomy. The symptoms were particularly obvious after big meals, which suggested a mechanical factor—an idea supported by the patients, who found that they could reduce the symptoms by limiting the bulk of the main meal. To elucidate the relative parts played by mechanical effect and by hypoglycaemia the results were compared of giving 50 g of glucose in water on one day and a bulk meal containing very little carbohydrate (6 g) on the following day. Serial blood-sugar estimations were made and the presence of symptoms recorded. In 16 out of the 24 cases the symptoms were more pronounced after the bulk meal, in four the severity of the upset was equal, and in the remaining cases the glucose drink caused most discomfort. It seemed, therefore, that bulk rather than the carbohydrate content was to blame. Hypoglycaemia was certainly not responsible, as all the symptoms occurring after the glucose drink were associated with a normal or raised blood sugar. Irvine's observations therefore support Adlersberg and Hammerschlag's contention that mechanical factors are responsible for the early symptoms. All his patients, however, had been operated on recently, and none had developed the late post-prandial symptoms which come on two to three hours after a meal. It is possible that these may not appear until months or several years after the partial gastrectomy, as in the three cases described by Barnes. There seemed to be no doubt that his patients were suffering from hypoglycaemia. The fact that the early and late post-prandial symptoms are similar does not exclude the possibility of two different mechanisms being responsible. Irvine suggests that adrenaline over-secretion may be produced by distension of the gut, and there are certainly points of symptomatic similarity between hypoglycaemia and excess of adrenaline secretion. This conception is of particular interest in view of the similar syndrome which is known to follow vagotomy for duodenal ulcer, and careful observation of these cases is indicated. A further study of early and late post-prandial symptoms is needed in correlation with different types of gastrectomy.

### NINTH INTERNATIONAL CONGRESS ON INDUSTRIAL MEDICINE

The Ninth International Congress on Industrial Medicine is being held in London from Monday, Sept 13, to Friday, Sept 17. The Congress is held under the auspices of the Commission Internationale Permanente pour la Médecine du Travail, which was founded by Luigi Devoto in Milan in 1906 to study questions concerning industrial medicine and to establish permanent relations between those who work in this field in different parts of the world. The original aim of the Commission was to hold congresses at regular four-yearly intervals, but two world wars have interfered with this plan. The last Congress was held in Frankfurt in 1938.

The opening session of the Congress next week is to be held in the Central Hall, Westminster, SW 1, at 11.30 a.m. on Monday, when the chair will be taken by Lord Moran, P.R.C.P., and the inaugural addresses will be given by the Rt Hon G A Isaacs, M.P., Minister of Labour and National Service, and Mr T E A Stowell. At the closing session, also in the Central Hall, at 2.30 p.m. on Friday, with Lord Webb-Johnson, P.R.C.S., in the chair,

<sup>1</sup> *Lancet* 1947 2 536

<sup>2</sup> *Surgery* 1947 21 720

<sup>3</sup> *British Medical Journal* 1947, 1, 330

addresses will be given by the Rt Hon G R Strauss, M P, Minister of Supply, Sir Ewart Smith, Professor P Mazel, and Professor L Carozzi. The very full programme which begins on Monday afternoon is divided into a number of sessions concerned with the various aspects of industrial medicine, and for the first time in the history of the Congresses the subject of industrial nursing has been included. Delegates from over 23 countries are attending the Congress, and it is hoped that there will be at least 1,000 delegates present during the week.

Those diseases of the lungs caused by metals and organic material will be discussed, and special attention will be paid to the pneumoconioses. Recent advances in the study of the problem as it affects the coal-mining industry in Great Britain, particularly in South Wales, will be described by a team of workers whose contributions to the study of this condition are already well known. Such distinguished workers as Professor Phillip Drinker, of the United States, and Dr A J Orenstein, of South Africa, will receive an especially warm welcome from the British Organizing Council. The study of disease prevention, which is the keynote of industrial medicine, will be given special consideration, and one session has been devoted to preventive methods in mining. Experts from a number of countries are to read papers on the organization of industrial medical services, on the training of industrial medical officers and industrial nurses, and on the medical content of the law as it applies to industrial medicine. The study of the industrial environment, chemical, physical, and psychological, will be amply covered, and five sessions will be devoted to the study of industrial toxicology and the effects of the newer metals. There will also be a discussion on the hazards of radiant energy and their prevention. A new feature in the programme is the inclusion of a session on architecture in its relation to the industrial environment, and two specialists in this field will be speaking on the subject as it affects both miners and industrial workers. Papers on the highly specialized subjects of industrial diseases of the skin and of the eyes will be presented by experts in this field. At the close of the Congress the Mackenzie Industrial Health Lecture on the surgeon in industry will be given by Mr H E Griffiths in the Great Hall at B M A House.

At no time in our industrial history have the health, happiness, and efficiency of the industrial worker been of greater significance than they are to-day. Sir George Schuster's views on human relations in industry are presented at length in the opening pages of this issue and are the subject of comment also in our first leading article. At the Congress the problems of human relations, of incentives, skill, job adjustment, and absenteeism will be reviewed by experts from the United States, Canada, Great Britain, France, and Belgium, and important papers will be read by Professor Elton Mayo and Professor Sir Frederick Bartlett.

#### "BRITISH JOURNAL OF INDUSTRIAL MEDICINE"

Next month the *British Journal of Industrial Medicine* will have completed five years of life, and it seems appropriate, when the Ninth International Congress of Industrial Medicine is about to meet in London, to review its achievements. The enthusiasm of a small group of members of the Association of Industrial Medical Officers led by Dr Donald Stewart in Birmingham was responsible for the creation of the journal and it was a considerable

achievement to start a new journal in 1944—the fifth year of a world war. Sir Henry Bashford, then medical adviser to the Treasury, was the first editor, and it was under his guidance that the pattern of the journal was set. The first number contained articles on statistics, toxicology, environment, nutrition, and orthopaedic surgery. This in itself shows what a wide field had to be covered. The medical problems of such different industries as shipping, ship-building, chemicals, mining, catering, agriculture, and retail trading cannot be confined in a narrow specialty, and there is no branch of medicine which has not some representation in this journal.

Sir Henry Bashford resigned the editorial chair before the first number appeared in print and his place was taken by Dr Donald Hunter, whose indefatigable energy has carried the journal over every sort of obstacle from paper control to printing strikes, so that it is now a flourishing concern with a large circulation.

The journal has often had to face the criticism that it devotes too much attention to toxicology, but there have never been any grounds for this opinion, in fact out of 117 articles only 25 have been concerned with industrial toxicology. The wide scope of the journal is also shown by the diverse interests of the editorial committee, which includes a statistician, an orthopaedic surgeon, a toxicologist, a chest physician, a ventilating engineer, a professor of industrial medicine, and others interested in the social aspects of the subject. There have been many articles on the prevention of accidents, a topic regarded as of great importance by the Ministry of Labour and frequently discussed in the annual reports of the Chief Inspector of Factories. There have, however, been very few from the surgeons on the treatment of these accidents, and it is to be hoped that much more attention will be given to this subject. The excellent Liverpool Docks Medical Service has shown that efficient treatment of minor injuries can save an enormous amount of human suffering and disability. Besides the original articles the journal publishes book reviews, summaries of British and foreign official publications, proceedings of the Association of Industrial Medical Officers, and, by collaboration with *Abstracts of World Medicine*, an abstract edition, which is of value in keeping the industrial medical officer informed of work in foreign countries. From time to time critical reviews have appeared. The first, by Dr Thelwall Jones, of Liverpool, was on the subject of "Industrial Dermatitis." This was followed by the "Toxicology of the Newer Metals," an authoritative and complete account of a developing subject by Dr Lawrence Fairhall, of the United States Public Health Service, "Health Hazards of the Pharmaceutical Industry," by Dr R M Watrous, of Abbott Laboratories, Chicago, and the "Effects of Climatic Extremes," by Dr Macdonald Critchley.

Clearly the *British Journal of Industrial Medicine* is already playing a useful part in disseminating knowledge and in promoting interest in this growing specialty. Another annotation in this issue gives some account of the programme for the Ninth International Congress on Industrial Medicine. It is hoped to publish in the near future a special issue of the *BJIM* with papers and reports from the more important sections of the Congress.

Dr F M R Walshe, F R C P, F R S, will deliver the Harveian Oration before the Royal College of Physicians of London (Pall Mall East, S W) on Monday, Oct 18, at 3 p m. His subject is "The Structure of Medicine and its Place among the Sciences."

## THE FACTORY NURSERIES

BY

W E CAVANAGH, BSc (Econ), DPA

Since the end of the war a great many of the wartime nursery schemes operated by local authorities have dwindled or vanished altogether. This may be partly because the general public pressure in favour of nurseries has lifted and also because a more cold-blooded examination of the position has thrown doubt upon their value as a contribution to the solution of problems of labour shortage.

The main interest of the maternity and child welfare department of the authority is in the welfare of the child, not the economic productivity of the mother, and it is often the most necessitous rather than the most highly skilled mother whose child is admitted to the council nursery. From the point of view of labour supply there are too many loop holes, and it is not always possible for the nursery to maintain an accurate check on the attendance of the mothers at work or to evaluate the comparative national importance of the proposed employments of those on the waiting list. In addition the expense of the nurseries is very great and now falls to a far larger extent upon local funds than during the period of the wartime special grant. The local authorities are therefore showing some resistance to Government efforts to persuade them that it is the duty of the local ratepayer to make a substantial contribution for a generalized, and doubtful, return.

While the number of nurseries has declined, it is worth noting that this has been accompanied by a considerable increase in the number of nursery classes provided by the education authorities in the schools as part of the education service, and a great expansion of the school meals service. The staff used in the nursery classes is in the ratio of one to every seven or eight children as against one to four in many of the day nurseries, but otherwise some of the same objections apply, far more serious is the difficulty that they do not accept children under 2, and that they are normally open only during the usual school hours and during term time. They cannot take the place of the day nursery.

These changes have taken place simply as part of our general peacetime plan for normal social services. They are not intended to relate to our present situation, which is such that we are fighting for our lives in the export markets of the world and our labour supply position is worse than at almost any time during the war. Except in areas with a high concentration of export industries the picture does not present itself to the public mind with the sharpness of its ominous reality, and it is doubtful whether public opinion on the restarting of large-scale nursery schemes by the local authorities would in most areas be more than lukewarm, if not actually hostile. Against this background of doubt and hesitation a new development is being tried out on an increasingly large scale—the factory nursery.

Here the employer is responsible for the whole expense beyond what can be charged to the mother, and the cost is still near the 35s mark. Charges are low, and usually not on a sliding scale but on a flat rate varying from 1s to 2s per day in different factories for a five day week. This means that a net cost of 25s to 30s per child is being borne by the firm. In spite of this great expense the North-West Region, which contains almost all the factory nurseries now opened, presented the following picture at the time of going to press.

*Factory nurseries*

Open	66, providing	2,549 places
About to open	23,       "	875       "
In project stage	15,       "	570       "
Total		<u>3,994</u> "

Private firms do not lightly incur such costs as these. Their interest is in the freeing of mothers for factory work, and the schemes are well worth examination from the labour supply point of view.

### Administration of Nurseries

The key points are, of course, the staff used and the mothers released. Each factory need open its nursery only for the period covering its own full time day and can therefore usually manage to run on the number of staff officially recommended by the Ministry of Health—i.e., one to every five children. Many factories have maintenance and service staffs and a doctor actually on the spot or near at hand, and these can often include the nursery in their normal day. Nurseries may draw their food from the factory canteen and neither buy nor cook their own. The nursery is appropriately sited in the sense that no extra travelling time is required, and some firms collect the mothers and babies in a special bus each morning. The mother can often see the nursery garden and playroom from the windows of the factory.

The employer has a direct interest in seeing that the nursery is used by the mothers most valuable to him and will even hold a place open, refusing the applications of the less skilled if he has hopes of securing a worker in a higher category. He has also the best means of knowing exactly what work the mother is doing and whether she is actually at work. He does not allow the mother who takes a day off for shopping or an afternoon at the pictures to use the nursery while she does so, nor can she usually send the child while she is sick, since it is not primarily a welfare service but a very costly method of getting labour.

Most of the factory nurseries take only one child from each family as a rule, but some categories of labour (e.g., drawframe tenders in the ring spinning industry) are so vital—since their absence can cause a bottle-neck affecting a wide range of subsequent processes and numbers of other workers—that an employer may be prepared to incur the expense of two or even three children rather than lose the mother. There are similar instances of nurseries taking a child of over nursery age during the school holidays, or the child of a male key worker whose wife is sick and could not attend to it.

The nurseries are being allowed to recruit helpers of all ages over 15, and it is an interesting fact that while almost all other occupations can offer vacancies but cannot fill them the factory nurseries have no difficulty in obtaining staff. Some employers are even able to vary their staff from week to week according to the numbers of children being accommodated.

Most of these helpers are between 17 and 40 years old and could theoretically be employed in factory work themselves. They are unskilled, however, and presumably unwilling, and their usefulness would be small as compared with that of the mothers they now release. The more highly skilled the work in the area the more worthwhile the nursery becomes. In some areas where nearly all the work is skilled or at least requires a degree of dexterity only acquired after long practice as much as two thirds of the labour force is female and up to 80% of these are married. In the case of cotton a record of prolonged unemployment and bad conditions in the past has diverted the juvenile entry to other occupations. Until the new attractions of higher pay, shorter hours, more modern machinery, much better working conditions such as exist at many undertakings now, together with the new gain in national prestige, have had time to take effect, the outward flow will not be reversed. This may take a decade, and it is difficult to see what in the meantime is the acceptable alternative to nurseries. The size of the labour pool which they can hope to tap is indicated by the success of the housewives' evening shifts and the long waiting lists at all the nurseries.

There are areas where the labour-supply advantages of even the factory nurseries are not quite so clear—e.g., where the released mothers are doing work which is not so skilled that it could not be done by young unmarried women at present working in the nurseries. It must be realized, however, that the two groups—staff and mothers—have sorted themselves out into those who, on balance, prefer nursery to factory work and those who are willing to go into the factory. It is possible to criticize this solution from the point of view of the children, even against a background of bad and overcrowded housing conditions, low rations, and the difficulty of meeting the high cost of living beyond bare necessities out of one income. But those who do so must also face the realities of the present situation. They must be prepared to consider the alternative

of a return to wartime control of labour, of direction of women to work of the highest priority only, however "unsuitable," and of juveniles into the undermanned industries, whether in their own home towns or away, and the further alternative of much longer hours for men of all ages

#### Registration with Local Authority

There has been strong criticism of the nurseries themselves. Reference has been made in Parliament to "cases of bad overcrowding, premises deficient in ventilation or sanitary accommodation," and staff "completely untrained and not suited to the work." The Ministry of Health, though able to give priority in certain areas for building materials, etc., has otherwise had no more than an advisory function and could neither inspect nor control such nurseries.

The Nurseries and Child-Minders Regulation Act, which received the Royal Assent a few weeks ago, now lays the responsibility squarely upon the shoulders of the local welfare authority and the local medical officer of health. Nurseries are in future to be registered with the local authority, whose authorized representative may enter the premises at all reasonable times, if necessary on a warrant from the justices. The local health authority may require the appointment to the staff of persons qualified as they may specify and in such numbers as they decide. They can also require the adequate maintenance and equipment of the nursery, medical supervision of the children, and an adequate and suitable diet.

As one MP remarked voicing the general opinion "the regulations are wholly desirable." Nothing is required to be done before the expiration of a "reasonable time" from the commencement of the Act, and as the greatest difficulty is likely to be that of obtaining trained staff the interpretation of a 'reasonable time' must be liberal. Present economies of labour due to the supply of meals from the factory canteen may also disappear in some cases. But the advantages of the factory nurseries in regard to sitting and maintenance are solid, and the vital fact that the employers, who bear the cost, also select the users should ensure that they continue to make a real contribution to the solution of our labour problem.

## STREPTOMYCIN TREATMENT OF TUBERCULOSIS

### MINISTRY OF HEALTH STATEMENT

The allocation and distribution of streptomycin will henceforth be on a regional basis. The beds will be so staffed and equipped as to ensure the necessary scientific control of the treatment. It is therefore hoped that, so far as possible, doctors having suitable patients will endeavour to admit them to these beds.

In view of the recent and proposed future extensions of the scope of streptomycin treatment of tuberculosis in this country it is desirable that all who are likely to use the drug should be aware of certain limitations and dangers associated with its use. Even for the three types of tuberculosis (acute miliary, meningeal, and ulcerative tracheo-bronchial and laryngeal) for which streptomycin constitutes the best treatment yet found and appears to produce a cure, this is only in a minority of the meningeal cases, and it certainly does not produce 100% cures in miliary cases. Clearly, streptomycin is not a panacea even in these forms of the disease. By far the most important toxic effects of streptomycin are vestibular changes, compensation for which is visual and cannot therefore be achieved in a poor light.

The production of streptomycin-resistant strains of *M. tuberculosis* is, however, the greatest potential danger because it is two-edged. Thus a patient with very early pulmonary disease who might have responded to other recognized forms of treatment alone but who is given streptomycin "prematurely" may be found, in the event of relapse or extension of the disease, to be beyond the reach of streptomycin treatment. From the public health point of view there is clearly a risk of old chronic cases spreading infection with streptomycin-resistant strains—so that patients acquiring meningeal or miliary tuberculosis from them cannot hope, in their turn to be benefited by streptomycin treatment.

The Medical Protection Society records in its recently issued Annual Report that 1,501 new members have been elected. The short accounts of legal proceedings taken against medical men during the year—an inevitable and indeed increasing burden on our profession—are as instructive as ever. The Report comments on the large number of cases being reported where a syringe needle has broken in the tissues of the patient. The Society has such needles examined by a metallurgist, and it appears that the fault lies almost invariably with the needle. Practitioners are reminded that iodine should not be brought into contact with these needles, and they should be sterilized in such a manner that the temper of the steel is not altered. The Annual General Meeting of the Society will be held on Sept 12 after an Extraordinary General Meeting to be held on the same date.

### SIR JOHN HERBERT PARSONS

#### A Presentation Portrait

The members of the Faculty of Ophthalmologists and of the Ophthalmological Society of the United Kingdom subscribed to present to Sir John Herbert Parsons on his eightieth birthday his portrait painted by Mr John Gorlay. The presentation, the occasion for which was the subject of an annotation in our issue of Sept 4 (p 481), took place at the Royal College of Surgeons on Friday, Sept 3, in the presence of a large gathering of ophthalmologists from all parts of the country, others at the ceremony included Lord Webb-Johnson and Sir Henry Dale.

Sir Stewart Duke-Elder, in making the presentation, after speaking in feeling terms of his great personal indebtedness to Sir John, said that the portrait was given to signalize what its subject had done for British ophthalmology, and in the second place to express the feelings which his colleagues and former students had for him. Some of the younger men in ophthalmology might not be aware of all they owed to Parsons. Alike in clinical work, fundamental research, and publication and teaching he was *facile princeps*. Every ophthalmologist treated his patients better because of what Parsons had taught and written. He would be remembered for his work as a pioneer in ophthalmological pathology. In the fundamental sciences which underlay vision—the biological, physiological and pathological sciences—Parsons was still the greatest authority. In the organization and inspiration of research he stood almost alone. In all problems concerning sight, Government and industry had consistently asked and received his help. In international ophthalmology he had always been a leading figure and a constant and acceptable British ambassador.

Sir Stewart Duke-Elder went on to say, however, that in his opinion Parsons's greatest service to ophthalmology was something more subtle. Through him it had been possible to maintain continuity in the transition from the past to the future. When he was young ophthalmology was the scene of a great deal of individual research but later, and particularly during the inter-war period, largely because of the advance of scientific research in general it was necessary for individual to give place to organized effort, for which they were rather ill equipped and

ill prepared. It was certainly due to Parsons that individual scientific research in ophthalmology showed signs of reviving. Parsons had been largely responsible for instituting the Faculty of Ophthalmologists. The speaker hoped that in the new College of Surgeons the Faculty and the Society would have a council room of their own, and that in that room, when Sir John had no further use for it, this portrait would hang in the place of honour as a reminder to them all of his great service. The portrait was not only a mark of admiration and gratitude but a real expression of affection. In his long life Sir John had received many marks of recognition in high places, and British ophthalmology had given him every honour it was in its power to bestow. The portrait was a symbolic expression of the affection of three generations of British ophthalmologists who felt themselves deeply in his debt.

Lady Duke-Elder having unveiled the portrait, Sir John Herbert Parsons covered his emotion by embarking on some philosophical observations on portraiture and personality, adding only that no achievement could be greater than for a man to have gathered around him a group of faithful and affectionate friends.

## Reports of Societies

### BRITISH NEUROLOGICAL SURGEONS

#### Meeting in Dublin

The Society of British Neurological Surgeons held its thirty-eighth meeting in Dublin on July 29 and 30, under the presidency of Sir Hugh Cairns. Meetings were held in Trinity College by the courtesy of the Provost, and the programme was arranged by the regius professor of surgery, Adams McConnell. There was a large attendance which included corresponding members from Canada, Sweden, Denmark, and Spain, as well as British visitors.

The main item was a symposium on the surgery of the acoustic neuromas opened by Dr Gilbert Horrax, of the Lahey Clinic, Boston, Mass., and Professor Herbert Olivecrona, of Stockholm, whose paper had to be read for him as he was recovering from a recent attack of pneumonia. The discussion was continued by Mr D W C Northfield, Professor Jefferson, and Mr Pennybacker. It is hoped that a full account of this important review, in all of several hundred cases, will eventually be published.

Other items of interest were contributions by Sir Hugh Cairns on the treatment of subdural empyema, by Professor McConnell on subdural collections of fluid after head injuries, by Dr Allan Mooney on the cause of certain field defects by pressure on the optic nerves, by Professor Jefferson and Mr Richard Johnson on intracerebral bleeding from aneurysms, by Mr Dawson on the blood supply of the chiasma and optic atrophy from arteriosclerotic plaques in the walls of the carotid artery, by Mr Atkinson on brain-stem infarction from operative injuries of branches of the superior cerebellar artery, and by Mr Tutton on the superiority of facio hypoglossal over spino-facial anastomoses for facial palsy. Mr Dickson Wright showed a coloured film illustrating his special approach to the orbit for the removal of orbital tumours.

The Society's dinner was held in the Hall of the Royal College of Surgeons in Ireland, through the hospitality of Professor Meade.

The second meeting of the Scottish Society of the History of Medicine was held in the hall of the Royal College of Surgeons of Edinburgh on June 18, with Dr DOUGLAS GUTHRIE, the president, in the chair. Dr JOHN RITCHIE read a paper on "Quarantine for Plague in Scotland in the Sixteenth and Seventeenth Centuries." Dr Ritchie described the methods of quarantine and disinfection of ships and their cargoes, and the measures taken to deal with the crews and passengers by isolating them on various islands in the Firth of Forth and elsewhere. In 1627, "Laurence Cockeburn, surgeon," personally examined the crews of suspected ships in the Forth on the instructions of the Edinburgh magistrates. Cockeburn was therefore probably the first port medical officer in Scotland. It is hoped that the third meeting of the Society will be held in Glasgow in October.

## Correspondence

### Prevention of Dust Diseases of the Lung

SIR—Dr A Meiklejohn (Aug 21, p 399) asks us in relation to dust disease of the lungs, "What is the earliest harmful evidence in coal-miners at which the workman should be advised to give up his skilled occupation and seek alternative work, or in the language of the compensation schemes, what constitutes the disease to a dangerous degree?" We would immediately agree with him in stating that this question demands a clear unequivocal answer. Before such an answer can be given there are various points which require consideration. First, it has long been known that of men certified as suffering from pneumoconiosis at an early age a majority advance to massive consolidation some years after leaving the industry and become eventually totally disabled by their disease. It is evident that this state of affairs must not be allowed to continue and that ideally, at no time should any man become completely unemployable by virtue of pneumoconiosis, but again it must be remembered that the vast majority of ex-miners are, once their skilled trade is closed to them, only able to obtain manual work usually of a comparatively heavy nature. This statement is borne out by the obvious preference shown to young women and non-miners by the managements of factories in this area who employ by and large the minimum of ex-miners. One can see, therefore, that the ex-miner must be able to carry out fairly heavy manual work compatible with his age for the remainder of his life, in fact at no stage must he be more than 30 to 35% disabled.

In order to obtain this result, we would state definitely that with the knowledge available to us to day all men who show pin-hole nodulation should be removed from exposure to dangerous dust, the question of disability and compensation being a separate issue. In our opinion, this standard should prove satisfactory for men with exposure to dust of 20 to 25 years' duration. In the event of such changes becoming evident with 15 years' exposure or less, a somewhat severer standard must be adopted, and conversely, if pin-hole nodulation becomes evident only after 35 years' exposure, the standard may then be somewhat relaxed. Even with suspension from the industry at this stage it is possible that in some cases progressive disease might occur, but we feel that the proportion of cases so progressing would not be greatly in excess of the number of mine workers who could be expected to develop tuberculous disease of the lungs in any event.

Again, all cases of consolidation should be immediately removed from the industry as potential sources of tuberculous infection, and to speak of leaving such men in the industry "as their progression may not be dependent on further exposure of dust" is in our view equal to advising a man to leave his hand under a steam hammer, as once it has received one crushing blow no further injury can take place. Furthermore, we would repeat with the greatest possible emphasis the plea we have made over many years for periodic x-ray examination of the lungs of all mine-workers, this being the only means by which the disease may be detected and suitable action taken before eventual advance to total disability becomes inevitable. It has been our practice for many years to carry out periodic examination of the lungs of the majority of workmen in the anthracite area of the South Wales coalfield, and all too often we see men already in the late stages of the disease who have only recently noted any disability.

These then are an outline of our views regarding the stage at which men suffering from pneumoconiosis should be removed from dust risk. Perhaps Dr Meiklejohn, who has had considerable experience of this type of work, would be kind enough to give us his personal opinion. Dr C M Fletcher, in his second Goulstonian Lecture printed in the *Journal* of June 5 (p 1065) stated that "the urgent necessity for the institution of an appropriate system of periodical x-ray examinations, which alone can give our coal-miners security from pneumoconiosis, cannot be over-emphasized." "The sincerity of the industry's and the Government's concern with the health of the coal-miners will be

judged by the speed and thoroughness with which such a system is instituted in this country." At the present time the Government and the industry seem to be doing all in their power to prevent the development of such a scheme and to discourage private workers in this field. Furthermore, the power of suspension has now been removed from the Silicosis Board and the compensation payable to partially disabled workmen severely reduced. These factors will contrive to force many men to remain in the industry where they may or may not be under proper observation. If this state of affairs is allowed to continue and if no action is taken to combat these retrogressive changes which undermine many years of struggle, then a future which will be truly tragic is inevitable and many young men will join their fathers and grandfathers in the cemeteries of mining villages years before their time. Their epitaph may well be, "We died that nationalization might succeed"—We are, etc.,

### Artificial Insemination

SIR—Despite the risk of appearing unduly sensitive I am requesting you to allow me to reply in your columns to certain criticisms in the report of the Archbishop of Canterbury's Commission on Artificial Insemination bearing upon a memorandum issued by the Medical Defence Union. The Union's memorandum did not purport to be an exhaustive study of the subject from all angles, and thus the Union had neither the facilities nor the intention to undertake. It was written, as the headnote states solely with a view to the protection of practitioners who engage in the practice of artificial insemination. In these circumstances the criticism that the memorandum is "superficial" is entirely unjustified.

It is, moreover, stated that the memorandum is "grossly misleading," but no indication is given of the reason for the use of such strong language. The chapter of the report dealing with the legal aspects of artificial insemination fails to reveal any basis for the criticism, unless it be that the writers have confusedly attributed to the Union the authorship of an article in the *British Medical Journal* (1945, 1, 40) or assumed that the Union shared the views expressed by the three authors of that article. Should this be so, it is appropriate now to repudiate on the Council's behalf both the authorship of the article and agreement with the views therein expressed.

It is conceded, of course, that the Union's memorandum did not make reference to the difficulty that will arise over the registration of the birth of an infant resulting from AID since registration is not a matter with which the practitioner is normally concerned. The difficulty is a very real one, and to it further consideration will be given by my Council in the future for this constructive criticism we are grateful.

It is regrettable that the authors of the chapter in question should have thought it proper to publish strong condemnation of the views expressed by the Union in a matter of complexity and public importance without first giving to the Union some indication of their intention and an opportunity of expounding its views. The very eminence of the authors in their own field promotes an expectation that the usual courtesies would have been observed. It should further be noted that permission to publish the Union's memorandum as an appendix to the report was only sought when the report itself was in galley proof and at a time when the urgency of publishing the report precluded the Union from properly considering whether the memorandum—prepared as it was with a different object in view—was suitable for such publication. I add with regret that neither then nor at any other time was there any communication to the Union that the memorandum was or would be made the subject of criticism.

Considerations of space prevent me dealing fully with the contents of the report, and it must suffice to say that, except for the single matter mentioned above, there appears at present no need for the Union to modify in any way the advice to its members set out in its memorandum—I am, etc.

### Inclusion Bodies of the Erythrocyte

SIR—With reference to your annotation (Aug 28, p 431) entitled 'Inclusion Bodies of the Erythrocyte,' we should be obliged if you would allow us to refute an opinion you attribute to us. Referring to our publication on this subject you state, "They are convinced that the siderotic granules of Gruneberg are different from the Pappenheimer bodies." This is, indeed, a complete misrepresentation of our views, for on page 255 of the paper referred to<sup>1</sup> we stated, "In view of these considerations it would appear that the siderotic granules described by Gruneberg (1941a and b, 1942) and by Domiach *et al* (1943) are probably fundamentally similar to the Pappenheimer bodies."

On the other hand, we wish to emphasize our belief that these inclusion bodies which stain with Romanowsky stains and give a direct positive reaction with potassium ferrocyanide and hydrochloric acid, are fundamentally dissimilar from the siderotic granules described by Case<sup>2,3,4</sup>. The arguments supporting this belief were discussed in our paper, but it may be mentioned here that Case's granules differ in respect of occurrence, morphology, and staining reactions from the erythrocytic inclusions described by Gruneberg in curly-tailed mice, and by Pappenheimer *et al* and by ourselves<sup>1</sup> in man.

Your annotation also refers to our having collected some evidence that the granules of basophilic stippling due to lead poisoning are similar to Pappenheimer bodies. It may be of interest to note that we have extended our studies in this field and have confirmed that the basophilic granules of lead poisoning present many similarities to the Pappenheimer bodies as regards development, staining reactions in the bone marrow and in the peripheral blood, and the effect of splenectomy. This work has recently been submitted for publication—We are, etc,

### Production of Rh Agglutinins

SIR,—I must apologize to Dr R J Drummond (Aug 28, p 443) and Drs Sheila T Callender and Z V Paykoç (Jan 26 1946 p 119) for giving the impression that they suggested that patients suffering from certain diseases were more apt to produce antibodies. This idea was communicated to me in conversation, but I have quite forgotten with whom, or who originated the idea—it may even have been myself. I still think it is a hypothesis worth considering, and if anyone who has suitable patients available is able to test the idea the results, whether positive or negative, would be interesting.

I must apologize for a *lapsus ratiocinationis* pointed out by Professor Cappel—the product of the mating  $Rr \times rr$  is equal numbers of  $Rr$  and  $rr$ —not 3  $rr$  to 1  $Rr$  as we wrote. This error does not affect our argument or conclusions—I am etc,

London NW 10

GEORGE DISCOMBE

### Acute Porphyria

SIR—I read with great interest Dr Ernest Petric's article (May 15 p 926) on 'A Case of Acute Porphyria.' The article reminded me of a similar case published by me in 1917 (*Z klin Med* 84 3) which showed the typical symptoms of chronic porphyria including a positive benzaldehyde (Ehrlich's) test. Owing to some unusual features I should like to give a short summary of the case.

A 24-year-old girl was admitted to hospital suffering from frequent attacks of severe abdominal colic, negative family history. Case history: temporary amenorrhoea and irregular menses had been suffering from these attacks for last 4 years, thought by some doctors to be due to peptic ulcer, by others to be of nervous origin. After an attack she passed an acid cherry red urine darkening on standing and becoming brown red on longer standing. Trace of albumin, hyaline and granulated casts in the deposit. On addition of alkali the colour turned yellow but on acidification the red colour returned. Negative guaiac and distinctly positive Ehrlich's benzaldehyde tests. Pigments not soluble in ether. Prof Salkowski, who

examined the urine, reported pigment soluble in amyl alcohol, slightly soluble in acetic ether, positive Ehrlich test but negative urobilin test, spectroscopically the acid urine gave a diffuse absorption band in the region of the urobilin band. Salkowski came to the conclusion that the abnormal pigment was "probably so called 'skatol-red,' which, however, was not sufficiently well characterized." Hot baths with subsequent diaphoresis seemed to relieve the pain. Patient died 1½ months later in a coma which occurred suddenly with epileptiform convulsions in all extremities, jerking of the head to the left, and horizontal nystagmus.

The results of post-mortem examination were: atrophy of musculature, dehydration, slight oedema of pia, hypoplastic aorta, small heart with moderately hypertrophied left ventricle. Pathologist's report: cortex of kidneys much reduced, in periphery tubuli very much reduced, fibrosis and small cell infiltration, slight fatty degeneration in tubuli but more so in Henle's loops, a few glomeruli showing amyloid degeneration (these findings did not, in his opinion, justify the diagnosis "death from uraemia"), fatty degeneration in most lobuli of liver, slight proliferation and small cell infiltration of peripheral fibrous tissue.

In the light of present knowledge of porphyrins the described data—red urine pigment not soluble in ether but soluble in amyl alcohol and slightly soluble in acetic ether, negative urobilin and positive benzaldehyde tests, absorption band in the region of urobilin—seem, no doubt, to justify the diagnosis of coproporphyrin porphyria—I am, etc,

London NW 11

### Sturge-Kalischer-Weber Syndrome

SIR,—Dr C Worster-Drought (Aug 28, p 414) gives a valuable summary of the literature of this syndrome and describes a case of naevoid amentia with bilateral calcification of cerebral vessels.

A boy, aged 16½ years, was admitted to Cell Barnes Colony in 1939 and died of pneumonia in 1940. He was a quadriplegic epileptic idiot, with but one cutaneous naevus above the nose and practically central. Radiographic examination showed evidence of much naevus on the left side and some to the right of the centre line. The specimen itself shows more than the radiograph suggests, the condition being most marked in the left temporo sphenoidal and occipital regions, but also present in the right frontal and parietal areas. This is the only true case seen at the Colony out of 1,300 admissions.

Another has the typical cutaneous naevus, widely distributed, right more than left, and is of imbecile grade. There is some evidence of paresis, particularly on the left, but no fits and no x-ray evidence of meningeal naevus. She is regarded as a probable but not proven example of naevoid amentia—I am, etc,

NOEL H M BURKE

### Dental Caries in Children

SIR,—Lady Mellanby and Dr Helen Mellanby (Aug 28, p 409) claim to have shown that better-formed teeth are less liable to decay. If they mean that such teeth are less liable because of their better structure their data seem to disprove the claim. They suggest that the lessened caries incidence in 1947 compared with that in 1943 is due to the better calcifying properties of the diet, and they also state that the actual factors initiating caries remain obscure.

To come to such conclusions they must ignore not only most of the work of other students of the subject but also some of their own findings. Although the data are not statistically analysed, it is apparent from Table IV that there is a very close correlation between hypoplasia and high caries incidence in 1943, but in 1945 this correlation is slightly reduced, and in 1947 it is very much weaker and possibly insignificant. This is because the caries incidence on the better-formed teeth has actually increased by 1947. The better the structure the greater is the increase, and the worse the hypoplasia the greater is the decrease in caries. Both increases and decreases between 1943 and 1947 appear to be significant for each grade of tooth structure. In other words, the decrease in hypoplasia incidence by 1947 has been most marked in the carious teeth and least in the non-carious teeth. It follows that improved structure cannot account for most of the decrease in caries, but only a statistical analysis could show how much, if any, it can account for. Certainly some other factors are responsible for much of the improvement, and these factors, which seem to

have been correlated with hypoplasia incidence in 1943, had almost ceased to be so by 1947. The correlation between structure and caries incidence in 1943 was not, then, mainly one of cause and effect, and thus most of the evidence for the authors' theory disappears.

The orthodox theory, which the authors consider obscure, explains the improvement as due to the change from a high-sugar and white-flour diet to one of whole vegetables, low sugar, and high-extraction flour. The 5-year olds examined in 1947 had been exposed for longest to the bulkier, more detergent, and low-sugar wartime diet. Apart from the lesser tendency of such diet to stagnate and ferment about any teeth, it also acts by promoting bone growth, and so preventing overcrowding of the teeth, and by removing other potential stagnation areas by attrition. Such factors begin to work almost from the time of weaning.

The correlation between caries and hypoplasia in 1943 and 1945 can only be explained by assuming that both are due to a common cause. The education of the mother might be a factor, but so little is known of the extent or the causes of variation in sugar consumption by young children that it is almost useless to speculate on the possible causes of the correlation. That sweet consumption varied widely before rationing is well known, and I have found that even now sugar and sweet consumption varies much more widely than one would expect.

It would not be worth while pointing out the fallacies in the authors' reasoning if they merely urged that we should consume more calcium, phosphorus, and vitamin D. However, they conclude that such is the *best* available way of attacking caries. Most well-informed students of the subject believe that a lower sugar consumption or higher fluorine intake, or use of a higher extraction flour, would, even separately, be far more effective, and it is even possible that caries could be entirely prevented at all ages by such measures used in combination—I am, etc.,

### Stainless Steel Wire

SIR,—Messrs A Lawrence Abel and Alan H Hunt (Aug 21, p 379) are to be congratulated on a splendid series of cases sutured with stainless steel. They have added materially to the evidence that one of the simplest, soundest, and probably the best method of repairing herniae is by darning. Also, they have shown that the use of a suitable non-absorbable suture obviates a preliminary attack on the patient's thigh or the effort to squeeze a last reluctant centimetre out of a strip of the external oblique aponeurosis.

I like their repair for incisional herniae in which they darn across the gap without drawing the edges together, but I shall try that principle only in the very large defects. I believe a continuous darn is unnecessary for femoral herniae, several interrupted sutures serving similarly and being easier to insert in the depths. I endorse their views on the use of a non-irritating, non-absorbable suture for closing abdominal-wall incisions, and particularly is it necessary to use such sutures in infected wounds and in cachectic subjects.

Unfortunately their incidence of sepsis in either clean or infected incisions is not mentioned, there being merely a hint that sepsis may possibly have occurred sometimes. This does not assist the judgment of others. I have tried using wire sutures and have found them rather difficult to manage, especially in the deeper tissues, and if one's assistants vary frequently the entanglements increase. At skin level wire is fairly easy to use. No doubt as the years go by the art, as in the case of these authors, can be successfully mastered at depth. My preference is for a suture which serves the same purpose but neither kinks, fractures, nor grates. In practice I find that nylon sutures are equally non-irritating, and behave well in infected tissues. A double strand of No 7 is strong enough for any closure or reparative procedure on hernia, and is easy to work with.

My own histological studies are on material from reopened wounds in humans, and for what any such studies are worth they indicate a very low level of tissue disturbance by nylon. My clinical results have shown a very low incidence of sepsis in clean and infected wounds, personal figures for clean darns in inguinal herniae being over 150, with sepsis once (in a scrotal

haematoma). Figures for infected wounds are being assessed on other types of cases. Criticisms of nylon are not justified when derived by inference from microscopical studies of various sutures buried in the smaller domestic animals, the only real test being what happens in cases. One cannot help wondering whether before darning with steel it is advisable to be sure that one's patient is neither a mariner nor an air pilot, and so liable to set the compass spinning after treatment. I presume the chances of being struck by lightning are not increased.

We are not yet finished in our hunt for the best suture material. Braided nylon, which I have recently tried, is beautiful to work with. Our present ideas of the virtuous monofilamentous strand may give way to a belief that the good behaviour of nylon and steel in infected wounds depends not only on their low irritation of the tissues but also on the fact that they are, unlike silk and cotton, non-wettable substances. Bacteria hiding between the strands of silk from hungry leucocytes has never strongly appealed to me as a theory. The answer may yet lie in braided plastic or braided metal. Perhaps when one of these industries is nationalized the resulting shortage may decide the issue for the other—I am, etc.,

Oxford

G E MOLONEY

### Diabetic Coma

SIR,—The letter by Professor D M Dunlop and Dr J B Donald (Aug 14, p 352) contains an important warning in connexion with the treatment of diabetic coma with large doses of insulin. This is that hypoglycaemia in an unconscious dehydrated patient is not always easy to recognize. This occurred in a patient, 67 years old, whom I treated recently for diabetic coma.

Using large doses of insulin intramuscularly as recommended by Professor R H Micks (July 24, p 200) but unfortunately without immediate blood sugar control (the patient was treated during the night), a fatal degree of hypoglycaemia was produced. This was only revealed by subsequent biochemical estimations of samples of blood taken at intervals during the night. The patient was carefully observed at half hourly or hourly intervals for any change in her condition, and particularly for signs of hypoglycaemia, but none were detected. Continuous intravenous saline was given. Three hours before death a blood sample (estimated later) showed the blood sugar to be 17 mg %, blood urea 78 mg %, and blood chlorides 631 mg %. At the commencement of treatment 14 hours previously the values were blood sugar 408 mg % and blood urea 101 mg %.

It is clear from such an experience that it is dangerous to give large doses of insulin to a patient in diabetic coma without facilities for *immediate* blood-sugar control. This particularly applies, as Professor Dunlop mentioned, when the treatment is in the hands of an inexperienced physician such as myself—I am, etc.,

HOUSE-PHYSICIAN

### Lumbar Sympathectomy for Varicose Ulcers

SIR,—I believe that Messrs John Borrie and E Vernon Barling in reporting (July 24, p 203) successful healing of four chronic varicose ulcers with lumbar sympathectomy have publicized a further remedy of this condition. I learned of it in 1946 from Dr Marcus Werquin, of Paris, a former assistant of Professor Leriche. He told me that he had used lumbar sympathectomy effectively in these cases, but it was before he knew of the operative treatment of varicose veins.

Since that time I have been looking for an obstinate ulcer in which lumbar sympathectomy seemed to be necessary. I have met two ulcers in my fairly considerable experience in the last three years which resisted the remedies laid down by Thomas Baynton in 1797 and retaught so ably by Mr Dickson Wright since 1929. The first man was not well enough for a sympathectomy, and I have had to admit failure. He had an ulcer which Baynton found resistant—I.e., below the external malleolus. In the second patient my friend, Dr Kenneth Wolferstan, of Sunbury-on-Thames, is achieving the healing which I failed to obtain. I mention these because I believe that the patients who require lumbar sympathectomy for the healing of varicose ulcers are very few if the ordinary remedies are faithfully applied.

For instance, in reading the case reports of Messrs Borrie and Barlings patients I did not think that they had received what could be regarded as an efficient operation for their varicose veins. In my experience no ligature, whether high or low, single or multiple, will permanently clear up varicose veins, ulcer, or eczema. I find that permanent effectiveness is attained only by high ligature, division of all the branches, and the certain destruction of the entire column of the internal or external saphenous vein from their beginnings at the malleoli to their endings. I think it is essential that treatment for varicose veins be thoroughly instituted before resorting to the attractive procedure of lumbar sympathectomy, which carries a mortality and will be followed by recurrence of the ulceration if the varicose veins, which are a progressive condition, continue to exercise their deleterious effects on the scar tissue about the ankle.

I agree with Messrs Dickson Wright, Rowden Foote, Kenneth Wolferstan, and others that all varicose ulcers can be healed if we will apply the supportive bandaging ourselves frequently and faithfully. I think that, while lumbar sympathectomy has a place in the treatment of ulcerated legs when complicated by arterial and trophic conditions, it is a small one—I am, etc.,

London W1

HAROLD DODD

### Genu Valgum

SIR,—Mr H. A. Brittain's article on genu valgum (Aug 21, p. 385) deals with the most common deformity of early childhood. Twenty-eight years ago, when rickets was still a common disease, it was the custom to take children with rachitic knock-knees off their feet or to put them in irons. Bony deformity and loss of muscle tone were the causal factors, and the latter was considered the more important. Immobilization in bed and to a less extent in irons aggravated the muscle weakness. As the orthopaedic surgeon rarely sees these cases until the children are 2 years or older, the aetiology and early treatment as seen and practised at an infant welfare centre may be of interest. These children were allowed to exercise freely, their heels and soles were wedged, and they were given intensive treatment for rickets. The results more than justified the break-away from more orthodox methods.

In the far more common non-rachitic cases of genu valgum I believe the lack of muscle tone is the primary trouble and the stretching of the internal lateral ligament of the knee secondary to it. I have been struck by the fact that I see a larger proportion of children with knock-knees in private practice than I did over 20 years at an infant welfare centre. The explanation would appear to be that the children of the comparatively well-to-do spend more time in their prams and less on their feet than the children of the poorer districts, who run about during most of their waking hours.

The preventive treatment of genu valgum is attention to the musculature of the child throughout infancy. I need not detail the necessary measures here, but it is a fact that many infants with poor tone have to be 'taught' to use their muscles, and exercises in weight bearing should be practised from the third month onwards. This is particularly important for the heavy child. The first efforts at walking are made on a wide base which throws a strain on the internal lateral ligament of the knee—the better the muscle tone and balance the sooner the walking base narrows. If at 15 to 18 months there is any evidence of genu valgum the heels of the shoes are tilted  $\frac{1}{4}$  in, increased later to  $\frac{3}{16}$  in, and the 'gramophone record' referred to by Mr Brittain is put on. Exercises are prescribed especially those which strengthen the quadratus femoris. A favourite one is carried out as follows. The child sits on the floor in the crossed leg position facing his mother, who sits on a chair. She places her right foot as a steady block against the inverted sole of the right foot of the child and her left to his left. She then clasps his outstretched hands and teaches him to rise slowly to the upright position and then return slowly to the sitting position keeping the legs crossed and the feet inverted the whole time. At first she takes most of his weight but less and less, until he can do the exercise without assistance.

At two years or a little later the tricycle (kiddy-car) serves with one precaution as good exercise for the leg and thigh muscles. The wooden bar which runs from the seat to below

the handle-bars should be well padded, so that the child shoves on the pedals with the knees well apart and the legs and feet inverted. A similar arrangement can be made on a toy motor-car or engine with pedals. The more fortunate child with a pony has the perfect apparatus.

It was surprising to hear that Mr Brittain has dealt with 8,000 cases of genu valgum in 15 years. Preventive measures or early treatment should reduce the numbers reaching the orthopaedic surgeon almost to zero—I am, etc.,

Esher Surrey

ALLAN HAMILTON

### Procaine Metabolism

SIR,—Procaine metabolism has been investigated during the last 15 years with growing intensity. Althoff<sup>1</sup> recently summarized facts and theories in a German publication. Thus, I hope, some findings dealing with the mode of action of procaine will be of general interest.

Recently Burgen and Keele<sup>2</sup> investigated the quantitative metabolism of procaine in the cat by determining procaine and *p*-aminobenzoic acid blood levels. They found rapid and extensive hydrolysis after intravenous injections. Neither Burgen and Keele nor other workers in this field (Hazard and Ravasse,<sup>3</sup> Dunlop<sup>4</sup>) published data on the second product of procaine hydrolysis, diethylaminoethanol. In experiments on frog's muscle (rectus abdominis), using a modification of the Chang and Gaddum technique (Soehring and Wiedow<sup>5</sup>), we confirmed the decrease in the reaction to acetylcholine described by Riesser and Neuschloss<sup>6</sup> when adding procaine to the bath. We found that this effect is followed by a marked increase in the tonus of the muscle, while acetylcholine excitability simultaneously is restored. Using small concentrations of procaine the response to acetylcholine can surpass the initial effect. These phenomena can be produced in the same way by equivalent concentrations of diethylaminoethanol. Hauschild and Landbeck<sup>7</sup> found an important sensitization to adrenaline when traces of diethylaminoethanol were given.

Modern procaine therapy thus appears as a special form of sensitization to adrenaline and acetylcholine, due to diethylaminoethanol set free by hydrolysis. The mode of action of this interesting compound cannot be discussed here in full detail. Its activity on surface tension<sup>8</sup> may be considered, as well as chemical composition, in some step of the choline metabolism<sup>9</sup>—I am, etc.,

### Gynaecological Psychiatry

SIR,—I have read the article by Mr Linton Snaith and Dr Brenda Ridley (Aug 28, p. 418) with great interest. There is, however, one problem fundamental to investigations of this kind, so far as the question of female orgasmic ability is concerned, which the authors have left unanswered and unsolved. What is a 'normal woman'? All investigators agree that 40–50% of their women patients show lack of orgasmic ability, and most authors regard this as a deficiency, physical or, mostly, psychological, that can and must be cured.

But before making this assumption would it not be our duty to prove to ourselves that the 'normal woman' is endowed with an orgasmic ability as universal and automatic as the man? In my opinion this assumption, so universally made, cannot be proved. As Terman has pointed out in *Psychological Factors in Marital Happiness* 'Woman's susceptibility to orgasm is either an evolving trait not yet fully established in the phylum or a regressive trait on its way out'. And since we can know next to nothing about the remote psychological past of the human race our only way to answer this question is to investigate whether or not female orgasmic ability could have played any part in facilitating the survival of the human race. It does not seem to have such significance.

To all bisexual organisms where successful copulation is absolutely necessary for the survival of the species, orgasm in the male acts as a fixing sensation additional to the organs of fixation, genital and extragenital, otherwise developed. With a few exceptions, most interesting in their appearance but which cannot be described here, the part of the females is so passive that they would not submit to copulation at all if they were not, during a particular season, stimulated hormonally to do so. They cannot, once copulation has begun, interrupt it of their own will. Fixation, physical and psychological, is exclusively achieved by the male, and this is true right up the evolutionary scale even to the anthropoid apes.

It remains for the psychologists to tell us why, in the absence of any phylogenetic history of female orgasm, the human female should in 40–50% of their number show orgasm ability. In my opinion this ability is linked up with the development of human self-consciousness, and I am inclined to regard female orgasm ability as "an evolving trait not yet fully established in the phylum." But I would refuse to assume that every female patient had already achieved or been born with this full degree of orgasm ability and should therefore be "cured" if found deficient.

Ever since and before van der Velde this assumption has led to great disappointment in doctors and patients, and while enlightenment, sex education, and treatment of all kinds do cure those cases where orgasm ability is only repressed by circumstances, it does nothing for those where this ability is non-existent. It makes the patients feel they are human freaks and leaves them more disappointed than if no cure had ever been attempted. It would be most interesting to hear from Mr. Sneath and Dr. Ridley what percentage of cases under their care have in fact been cured and what was the fate of the "incurables"—I am, etc.,

Pinner, Middlesex

EDWARD ELKAN

### Use and Abuse of Tonsillectomy

SIR,—I have read with interest the correspondence on the "Use and Abuse of Tonsillectomy," as it touches on a problem which frequently confronts the general practitioner. Dr. A. G. Newell (Aug. 21, p. 398) suggests that the decision for removal of tonsils and adenoids be left to the parents. I hardly think this is practicable, as most parents go to their doctors to be advised, and doctors as a rule do not dictate to them as to necessity.

Clinically I doubt if there is any more satisfactory operation in childhood than the removal of septic tonsils and adenoids. The ailing child, with frequent colds, gastric upsets, attacks of earache, and even running ears, seems to improve remarkably after the operation.

Up to the age of 3 to 5 years the tonsils and adenoids act as a defence and filter, preventing entry of infection into the blood stream. With each attack they form antibodies and confer an immunity against infection by countless organisms, which last until late in life. But once this function is performed they cease to be an advantage to the body, and are often only collections of pus and a frequent source of infection. At least in cases where pus is obviously present, with tonsillar glandular enlargement and obstruction to breathing, the parents should be advised that the removal of the child's tonsils and adenoids should be performed.—I am, etc.,

### Tonsillectomy or X-ray Treatment

SIR—No reference has been made to x-ray treatment in the interesting correspondence following the enquiry of Mr. William Ibbotson (May 22, p. 1002) as to what can be done for the many children awaiting tonsillectomy. X-ray treatment is a most valuable alternative to operation, as the tonsil is one of the most radiosensitive parts of the body (as Regaud pointed out about 1904). In children, quite small doses usually reduce the tonsil (and adenoid) enlargement to normal, and lead to rapid benefit in the general health, as I have shown in the *Journal* (1930, 1, 216 and 1197, and 2, 228, and 1932, 2, 665).

In the technique large doses and large fields should be avoided, the best results have followed small fields behind and below the angle of the jaw (or also from below and behind the mastoid) converging on to the tonsil. Doses of 100 to 200 r

weekly or fortnightly will be found to lead to rapid improvement in most cases, and operation can be rendered unnecessary. Once the tendency to physiological hypertrophy has been outgrown the tonsils, in cases followed up, have shown no further enlargement or infection.

In this method there is no risk of skin change even in blondes and the vicious circle of hypertrophy leading to crypt-blockage and infection is broken so simply, and with such restitution to the normal of a structure which probably has a useful function, that x-ray treatment should be regarded as the treatment of choice. That it has not come to be so considered is probably due to a too exclusively surgical approach to the subject, and to the preoccupation of most radiotherapists with the more pressing problems of cancer—I am, etc.,

J. H. DOUGLAS WEBSTER

### Prevention of Venereal Disease

SIR—Both Lord Horder (July 17, p. 171) and Dr. R. A. Lyster (Aug. 28, p. 441) seem to rely mainly on the opinion of the Trevethin Committee contained in the sub-paragraph of para. 11 of their report, which was quoted by Lord Horder. It seems to me that it would have been fairer to quote also the qualifications with which the Trevethin Committee guarded their opinion. The following extracts from the Report seem to be pertinent.

"13 We think, however, that we are justified upon the evidence in coming to the following conclusion. That in a community where there has been efficient instruction and where there is such a condition as arises from the control and influence mentioned above substantial results may reasonably be expected to follow from prophylactic measures but that the actual result is often less favourable than has been claimed."

In this "the control and influence mentioned above" refers to conditions in the fighting Forces. With regard to these the Committee said (para. 12)

"Where satisfactory results were recorded, a great difficulty arises in determining how far those results were due to the prophylactic methods employed, or were influenced by other factors in the case, such, for example, as regulation of hours of leave of absence, control of or exclusion from dangerous places, liquor control, imposition of penalties upon men becoming infected, the provision of facilities for recreation and the moral effect in time of war of appeals for restraint on grounds of patriotism. Further, the prevalence of disease among women has probably varied widely in different areas and it has rarely been measured."

The recommendation that the law should be altered to permit properly qualified chemists to sell *ad hoc* disinfectants was qualified by the following (para. 14)

"provided such disinfectants are sold in a form and with instructions for use approved by some competent authority. We suggest that the Medical Research Council should be invited to undertake this task. We think, however, that the commercial advertisement of *ad hoc* disinfectants should be prohibited."

Neither the M.R.C. nor any other authoritative body has undertaken the task. The Committee concluded on the subject of self-disinfection by saying

"16 In conclusion on this head, our view is that money spent on a general system of providing facilities for self-disinfection would certainly be less profitable than money spent either on treatment of disease or on those measures of education and improvement of social conditions to which we have referred above."

As I have taken a close interest in the prevention of venereal diseases for over forty years, studying methods and rates in our own and other countries whenever I could find them, I should like to describe here modifications made in my own views on prophylaxis by self-disinfection during that period. Until 1919 I was an enthusiastic advocate of the method, and when, in 1918, the D.G., A.M.D., Sir John Goodwin, asked my opinion on the probable effect of its introduction into the Army, I predicted a rapid emptying of military V.D. hospitals. In accordance with my advice, D.D.'s M.S. of the different commands in this country were made personally responsible for furthering the method by every means in their power, and inspectors were appointed to see that the facilities were freely available without any soldier having to ask specifically for the chemicals. I watched the V.D. rates in the Army at home very closely, and at the end of eighteen months had to admit that the matter was not proving so simple as I had at first thought.

At this time there was a strong agitation for broadcasting advice on the subject of self-disinfection to the civilian public. It was pressed with such claims for its probable effect as that, under it, V D in this country would quickly reach the vanishing point, and some advocates held that, considering that we had such a simple means of preventing these diseases, it was a waste of public money to provide facilities for their free treatment. My experience of its use in the fighting services had, however, taught me that, although it might eventually succeed in conditions permitting personal instruction, it would never do so in an undisciplined community instructed only by pamphlets. I stated this view at a meeting of the Royal Sanitary Institute in 1919 before I knew the views of the Local Government Board on the question. Further, it seemed to me that if, under such conditions, public health authorities advocated self-disinfection as a means of prevention of V D, sexual promiscuity would increase and the increased numbers of exposures to infection would not be counteracted by the measures advocated, the result would be an increase in V D. On the question of fear as a deterrent from extra-marital intercourse which is implied in this opinion, the Trevethin Committee held a different view, since they said

"It is urged by some that any system of disinfection would tend to increase the number of exposures and to raise the disease rate. We have received no evidence of facts in support of this view and we are inclined to think that those who hold it attach too much weight to the deterrent effect of the fear of disease."

It is questionable whether the Committee would have held this view if they had had the evidence which we now have of great increases in the incidence of V D in the armed Forces since the men learnt how easily gonorrhoea is cured by penicillin.

Dr Lyster says that many witnesses before the Trevethin Committee, including himself, "produced overwhelming evidence of the dramatic reduction in V D that follows the introduction of self-disinfection." The Committee does not seem to have been made wildly enthusiastic for a policy of self-disinfection by this evidence. As part of my own evidence before the Committee, I prepared a critical review of all the evidence I could gather from the literature and elsewhere on the value of disinfection, both skilled and self-applied, in the prevention of V D. It was a lengthy document, of over 25,000 words, its prolixity being due to long quotations, with all statistical tables, from the works studied. Before sending it to the Trevethin Committee I submitted it to criticism by an eminent medical statistician, who made many valuable amendments. I read the evidence given before the Committee and did not find in that submitted by Dr Lyster any new facts to alter the conclusions I had drawn from my review. If Dr Lyster has conclusive evidence on the value of self-disinfection I suggest that he give it now after submitting it to examination by a statistical expert. My own view that self-disinfection has not succeeded even in the favourable conditions provided by the armed Forces has been strengthened by the high rates in those stationed in highly infected communities. If it fails in such circumstances, how could it succeed with civilians instructed only by printed matter? I agree with those correspondents who believe that broadcasting advice on the lines advocated by the NSPVD would be harmful by increasing the incidence of V D—I am, etc.

## POINTS FROM LETTERS

### Treatment of Chronic Varicose Ulcers

Mr N N TERESHCHENKO (Wandsworth, London, SW) writes. In connexion with Dr P E Roland's letter concerning the treatment of chronic ulcers (Aug 21, p 399), may I inform him that division of cutaneous nerves was first described by John Hilton (see *Rest and Pain*, pp 148-52 in the 1905 reprint of the 5th edition)?

### Treatment of Typhoid Carriers

Dr ARTHUR COMPTON (London NW) writes. In view of the somewhat disappointing results reported by Dr R M Fry and others (Aug 7, p 295) of the treatment of typhoid carriers with sulphadiazine, penicillin, and of your annotation thereon (p 305) may I call your readers attention to the account of a successful clearing up of the carrier state after various treatments, including sulphadiazine, which I failed to do so (Compton J R *Egypt med* 1947, 18: 26-27).

## Obituary

### J K JAMIESON, M B, LL D

Professor J K Jamieson, who died at his home in Blackro on Aug 20 at the age of 75, had been professor of anatomy at the University of Dublin from 1936 until his retirement last year. Previously he had been professor of anatomy in the University of Leeds for twenty-six years, and dean of the medical school there for nearly as long. John Kay Jamieson, the fourth son of Robert Jamieson, of Sandness, was born in Shetland in 1873. From the Madras School he went on to the University of Edinburgh, where he graduated M B, C M in 1894. He was chief demonstrator in anatomy at Surgeons' Hall before taking up a similar appointment at Leeds. He worked there under Wardrop Griffith and succeeded him as professor of anatomy in 1910. It was during the 1914-18 war, when he was acting as deputy dean of the faculty of medicine, that his notable administrative ability was first shown. At this time he was also registrar and later in command of the East Leeds War Hospital in Beckett Street. In this early period he made a number of valuable contributions to his own special subject, particularly on the anatomy of the lymphatic system. In this connexion his studies of the lymphatics of the tongue and of the colon were notable and have since come to be regarded as classic contributions to surgical anatomy.

Jamieson was a man of sound scholarship and impeccable integrity and for many years he dominated the Leeds medical school. He was, in the words of a colleague, "a remarkably good dean." He had the gift of making—without ever appearing to do so—a number of individuals of diverse character and interests work as an effective team. He was wise and far-sighted, and it was largely due to him that the faculty expanded so effectively, particularly in the department of physiology and in the establishment of the Algernon Firth Institute of Pathology. From 1928 to 1936 he was a member of the General Medical Council, and he was also acting as examiner for the universities of Aberdeen, Belfast, Bristol, Edinburgh, Liverpool, Manchester, and Sheffield. When he retired from the Leeds chair of anatomy early in 1936 tribute was paid to his wise judgment, his tact, his ingenuity in handling difficult situations, and his uniformly imperturbable good temper in the conduct of business.

Jamieson was then 63 and known throughout this country as a first-rate teacher of anatomy. Already many generations of Leeds University students had reason to be grateful to him. He was appointed to the chair of human anatomy at Trinity College, Dublin, in March, 1936, and continued in active work for a further eleven years. He succeeded Professor A F Dixon and was given the task of reorienting a department which was still faithfully conducted in the tradition of D J Cunningham. His lectures were always appreciated, but he excelled in informal teaching in the dissecting-room. He never forgot a student, and there were few whose admiration and respect for him was not tinged with affection. Beneath his rather forbidding exterior there was great kindness, a sense of humour and much modesty about much learning.

Professor Jamieson was a member of the Royal Irish Academy, a keen golfer, and interested in deep-sea fishing. He married Elizabeth, daughter of Dr R P Goodworth, and she died in 1936. He is survived by a daughter and a son, Dr John Jamieson. John Kay Jamieson was an outstanding anatomist, a fine administrator, and a remarkable personality who will long be remembered by his friends, his colleagues, and the many students he trained in Leeds and in Dublin.

Mr P R Allison writes. When, as a student, I first met J Kay Jamieson he was professor of anatomy and dean of the faculty of medicine. At what age his personality became fixed I do not know, but certain it is that for the twenty years I knew him he remained unalterably and imperturbably J Kay Jamieson. Therein lay his immense popularity with all students, for he was a rock of reliability in a rapidly changing world. The Leeds school and its students meant so much to him that he must have enjoyed the affection with which he was regarded, but he never sought popularity or praise. He was unmoved by the winds that blew, whether they were gentle or harsh. He

had some sort of sympathy with every kind of student, good or bad, hard working or slacker, for he did not judge men only by their ability to study medicine, yet his counsels were wise, considered, and free from prejudice, and often not what his supplicant wished to hear. He would give advice when consulted, but he rarely explained the reasons for his advice, it might be accompanied by a parable or proverb, but the foresight on which it was based usually became apparent afterwards. His quiet joy at the success of his students and his colleagues was infectious, so that none of us had any doubts but that Leeds was the best medical school in the world. He was in fact a leader. He treated everyone as grown-ups and expected them to behave like this within reasonable limits, so that he never found it necessary to have an attendance book at his lectures, and it was only the occasional "chronic student" who failed to attend.

His lectures must have been carefully studied and distilled, for they were virtually the same throughout the years. He spoke so steadily and used so many simple diagrams that the lectures could be taken down word for word, and we used to write down the jokes as well. When working for the primary fellowship I attended some of his lectures again and found that I could keep one sentence ahead of him all the time by referring to my original notes. Yet somehow he took the dryness out of the bones and put it into his humour and his mannerisms. His diagrams had been reduced to the simplest and clearest, and he obviously enjoyed drawing them. When he drew a perfect circle standing sideways to the blackboard and swinging his arm round at the shoulder, or when he drew a perfectly symmetrical thorax using both hands at the same time, he always roused the cheers and stamping which brought a twinkle to his eye and a slight elevation of the corners of his mouth. The graceful lifting of the hand to indicate that the applause was enough had in it the same confidence of obedience as that of the most accomplished policeman at a London crossroads. He appreciated the importance of physiology, but was justly content to be an anatomist. He taught form in relation to function without recourse to the muscle-nerve preparation, and when once consulted by Moynihan (of whom he spoke affectionately as "our Berkeley") about the feasibility of a particular operation he replied that "the limits of surgery are physiological and not anatomical".

After he had gone to Dublin I often wrote to him about problems of lymphatic anatomy in relation to surgery, but he retained a notable reticence and modesty about his specialty, and his letters often contained answers which were too honest to be really informative. He would write, "The subject needs a determined new survey. When our knowledge is assembled there is no clarity in it. Few realize that the distribution of the absorptive capillary network is very limited, little is known about the continuity of that network, there is a great deal of confusion about 'perivascular lymph spaces', a great deal of our traditional descriptive anatomy is mere lively imagination and assumption taken from the magnificent drawings of the early workers with mercury who must have gone by the motto, *Ab hoc uno disce omnes*". Yet he also gave encouragement for about excision of malignant disease he would say, "It's wholly a question of surgical experience as to whether it's worth doing, it's up to you to try". Jamieson was a man from whom a little encouragement was exhilarating, his slight jerk of the head—while looking over the top of his glasses—was enough to determine the direction of a career.

#### J G WILSON, M.B., C.M.

Dr John Gordon Wilson, professor emeritus of otology and chairman of the department of otolaryngology of the North-western University of Chicago, died on Aug. 13 at the age of 89. He had devoted himself to the study of aural anatomy and pathology for half a century, and was one of the best-known workers in this field in the United States.

A native of Edinburgh, he followed his graduation in 1890 at Edinburgh University with a period of foreign study in Berlin and Vienna, and particularly in Ewald's laboratory in Strasbourg, where he laid the foundations of his early work on *intra-vitam* staining. He returned to practice in Glasgow with an appointment to the staff of the Victoria Infirmary, and continued his researches into the anatomy of the ear and of the atrio-ventricular bundle of His. Impatience with the restric-

tion of animal experimentation led him in 1900 to leave this country for a fellowship in anatomy at Chicago University. It was not long before the value of his work was recognized, and he became an assistant professor. He retained a connexion with this country by spending his vacations in the laboratory of his friend Dr (later Sir Frederick) Mott at Claybury, where the abundance of fresh human material for anatomical study was an attraction. In 1908 Wilson was appointed professor of otology at the North-western University with which institution he was still in intimate contact up to the time of his death.

In the first world war his desire to be early in the field led him to join the Canadian Expeditionary Force which came over in 1915. This later prevented his obtaining American citizenship until after the lapse of a sufficient number of years. During the years that followed he was busy in practice and in research, investigating especially the more recondite aspects of his subject, as a list of his published writings illustrates. In addition to early papers on the bundle of His and the mechanism of vertigo, he made valuable contributions to our knowledge of the nerves of the tympanic membrane, the taste buds of the larynx, the comparative anatomy of the larynx of anthropoids, the utriculo-endolymphatic valve, and the patterns of the air-cells of the petrous temporal. Also well known were his studies of otosclerosis and labyrinthine disease.

In spite of nearly fifty years residence in the United States John Gordon Wilson remained a Scot. His speech and dry humour were typical, and as he advanced in years his nostalgia was shown by an increasing interest in the history of Scottish medicine. He contributed papers to various journals on this subject, and his last published work, which appeared just before his death, was a memoir of Dr Joseph Bell, the prototype of Sherlock Holmes, whom he clearly remembered from his student days. His work in otology gained recognition in the U.S.A., and indeed throughout the world. He was president of the American Otological Society and chairman of committees of the American Research Council on vestibular research and aural structure and function. He was a member of the Madrid Otolaryngological Society, and, most valued of all, member of the international Collegium Oto-Rhino-Laryngologicum Amicitiae Sacrum. Though afflicted in his later years by a failure of the organs to which he had devoted a lifetime of study, he retained the mental activity of a young man and an ability to keep abreast of the progress of science, not only in his own subject but in all branches of medicine, that was a continual source of wonder to those who had the good fortune to be associated with him. He died at the home to which he had retired in Old Bennington, Vermont.—G A E

Mr WILLIAM DAWSON GALLOWAY, one of the senior surgeons on the honorary consulting staff of the Huddersfield Royal Infirmary, died in the Infirmary on Aug. 2 at the age of 58. He was born in London and was a student at Clare College, Cambridge, and at Guy's Hospital. He qualified M.R.C.S., L.R.C.P. in 1914 and took the Edinburgh F.R.C.S. in 1919. Immediately after qualifying he joined the Royal Navy and served for five years both at sea and at the Naval Hospital in Malta. He was twice mentioned in dispatches. After several hospital appointments Mr Galloway started in practice in Holmfirth in 1922, and was made a member of the honorary staff of the Holme Valley Memorial Hospital. In 1930 he was appointed honorary assistant surgeon to the Huddersfield Royal Infirmary. He was also consulting surgeon to Storthes Hall Mental Hospital. In 1939 Mr Galloway took up residence in Huddersfield. He was a past president of the Huddersfield Medical Society. Mr Galloway was a man of outstanding ability. While running a busy practice in Holmfirth he took the F.R.C.S. in 1927. Then he gave up his practice to concentrate on general surgery. In later years his greatest interest was in gynaecological surgery. He was always very eager to help any young surgical enthusiast, but he did not suffer fools gladly, and demanded the best from all who worked with him. Apart from his surgical achievements he had many outside interests. As a young man, he was a proficient middle weight boxer, a keen rowing man, and a good "all the year round" swimmer. He also had a love of the bagpipes and was himself a player. He was a keen student of history and had a wide knowledge of military campaigns. His early death is a great loss to the Huddersfield district. Such was his zeal that he worked up to a few days before his death when he was obviously a very sick man. He will be sadly missed by his colleagues and by his many patients.—W S D

## Medico-Legal

### ACTION FOR NEGLIGENCE IN DIAGNOSIS

#### WHITFORD v HUNTER AND GLEED

In the Kings Bench Division, before Mr Justice Birkett, on July 6 and following days the action was heard of Mr James Forbes Whiteford, an American citizen, against Mr J B Hunter, MS, FRCS, and Dr Seymour R Gleed. The plaintiff's claim was that in 1942, when the defendants were called in to advise him on the state of his health, they diagnosed his complaint as inoperable cancer of the bladder, and stated that his life might not be very long extended. He had thereupon given up his home and business in this country and returned to America, but in New York, some five months after this diagnosis had been made, he was examined by an American surgeon, who operated on him and found an inflamed bladder and fibrous prostate but no evidence of cancer.

Mr Richard O Sullivan, KC, and Mr Robert Fortune, instructed by Messrs Billingham, Wood, and Pope, appeared for the plaintiff and Mr Cecil R Havers, KC, and Mr H C Dickens instructed by Messrs Hempsons on behalf of the Medical Defence Union, appeared for the defendants.

The learned judge found that the plaintiff was entitled to damages against Mr Hunter, and these were assessed at £6,300. Judgment was accordingly given against Mr Hunter for that amount with costs stay of execution being granted on the usual terms. It is understood that an appeal has been entered. Judgment was given for Dr Gleed, the second defendant, with costs.

#### The Facts of the Case

From the opening statement it appeared that in March, 1942, Mr Whiteford consulted Dr Gleed for bladder trouble. Dr Gleed examined him and suspected an enlarged prostate, but it was agreed to call in a specialist, and the patient was examined by Mr Hunter, who found acute retention due in his opinion to the state of the prostate gland, and advised immediate draining of the bladder to be followed at a later date by the removal of the prostate. The bladder was accordingly drained suprapubically, and Mr Hunter attended a fortnight later, on April 5, for the purpose of performing the operation. He found a hard indurated mass in the base of the bladder running backwards from the trigone about the size of the palm of a man's hand. He came to the conclusion that the mass was a carcinoma of the bladder of infiltrating type, that the tumour could not be operated on, and that it would be unwise to do anything further. He therefore closed the greater part of the bladder, leaving a tube for the purpose of drainage. Dr Gleed was present at this operation but it was Mr Hunter who was in charge. On being informed of the position the plaintiff went to America partly in order that his wife might be placed in the care of his brother but in September 1942 in the Memorial Hospital New York he came under the care of Dr Benjamin S Barringer who made a cystoscopic examination under spinal analgesia and took specimens for pathological examination. Dr Barringer came to the conclusion that the patient had a diverticulum of the bladder, with prostatic enlargement causing urinary retention. At operation he found the bladder inflamed but no evidence of cancer. He removed a large portion of the fibrous prostate. After some further treatment including electrical cauterization to remove further pieces of the prostate the plaintiff recovered and in 1944 returned to this country. The writ was issued in November 1945.

#### Case for the Plaintiff

The only medical evidence given on behalf of the plaintiff was that of Dr Benjamin S Barringer of the Memorial Hospital New York a specialist in genito-urinary surgery. The evidence had been taken on commission. Dr Barringer stated that he saw Mr Whiteford on Sept. 6 1942. On cystoscopic examination he noticed several small areas on the wall of the bladder the nature of which he could not understand.

he took a specimen for pathological examination, and it showed chronic cystitis but no evidence of cancer. He also saw the opening of a diverticulum in the base of the bladder. Accordingly he operated on the plaintiff on Sept 15, and found an inflamed bladder, a small fibrotic prostate, and in the bladder itself the opening of a diverticulum, which was filled with calcareous material. He opened up the diverticulum and he removed a large portion of the prostate. After excising the suprapubic sinus he closed the bladder and left a drainage tube in place. There was no cancer of bladder or prostate. He summed up the whole of Mr Whiteford's difficulties by saying that he suffered from a considerable bladder diverticulum and chronic cystitis.

Dr Barringer was asked

Assuming that Mr Whiteford's bladder had been opened on March 22, 1942, and again on April 5 in order that a prostatectomy, if necessary, might be performed, and a cancerous growth was then diagnosed, what steps in your opinion should have been taken to verify such diagnosis?—A complete examination by means of the cystoscope and through the open bladder, and a pathological examination of any questionable areas.

In your opinion would there have been at that time any difficulty in making a cystoscopic examination of him?—No.

Or any danger in making such an examination?—No.

Would there in your opinion have been any difficulty or danger in then obtaining a section for pathological examination?—No.

In your opinion that should have been done?—Yes.

A further question was

Was there anything you did, either in the examination of Mr Whiteford, the operation you performed upon him and the subsequent lesser operation which you performed, as well as the treatments you prescribed for him, which were in any way unusual or beyond the ordinary skill and treatment of the medical profession?—No, not if he were a competent urologist.

In cross-examination he could not agree that when a bladder had been collapsed it would be practically impossible or very difficult to pass a cystoscope, provided the bladder retained enough fluid—as it generally did—so that most of it could be examined. He also said that he had never seen the taking of a specimen from the bladder cause a perforation or observable ulceration, though anything could happen in careless and crude hands. In re-examination he was asked whether it would have been possible for Mr Hunter to have determined that cancer did exist without taking a specimen, and replied that that could have been determined, with all reasonable accuracy by looking at it and by the feeling of it. "You can tell a skin cancer across the street, practically, if you see it on the skin." He added that he had at first thought that perhaps the patient did suffer from cancer, but from the pathological examination and his examination of the opened bladder—a combination of the two, not the pathological examination alone—he decided that he did not.

#### Case for the Defendants

The principal witness for the defence was Mr J B Hunter, who was submitted to a long examination and cross examination. Questioned on the use of the cystoscope, he said that it was not his practice, when dealing with acute retention, to use this instrument, and this, in his opinion, was a case of acute retention. Asked by the learned judge to elaborate this, Mr Hunter spoke of the damage to the posterior urethra which might follow such introduction or attempted introduction of a cystoscope. Describing the indurated mass at the base of the bladder, he said that the mucous membrane over the mass was thickened, changed in colour, and had very indefinite edges. He came to the conclusion that there was a carcinoma of the bladder submucous and infiltrating and that it was too large to be removed. Asked about the desirability of taking a portion of the growth for examination, he said that he deliberately decided against that procedure because he felt that he would have to cut deeply into the bladder wall to obtain a suitable piece and that it was likely that he would go through the bladder and open up the spaces at the back of the bladder to infection. On the second occasion, that of the operation itself, he again did not use a cystoscope. It was a collapsed bladder, having had a tube in it for a fortnight, and in order to use the cystoscope it would have been necessary to distend the bladder with fluid to a considerable degree. The instrument which would have had to be used was the irrigating or flushing cysto-

scope, he had not such an instrument, and he saw no useful purpose likely to be served by such an examination.

Many points raised in cross-examination turned on the question of cystoscopy. The witness said he had already explained why he did not use a cystoscope. Mr Justice Birkett said that he quite agreed but he wanted Mr Hunter to understand to what the questions were directed. This was an important part of the case, because he apprehended that plaintiff's counsel was going to say that one of the acts indicating lack of care was the non-use of the cystoscope. If Dr Barringer could use it in September, and if surgical textbooks said that it was one of the chief means of examination, should he not have used it in March? Mr Hunter explained that when Dr Barringer used the cystoscope the conditions were entirely different. The bladder had been drained, and therefore presumably the condition of the mucous membrane was much healthier than when he himself had operated. The condition of the prostate itself was probably quieter, and the patient had got only a small sinus so that it was much easier to distend the bladder.

It was suggested by Mr O'Sullivan that Mr Hunter had "leaped" to the conclusion that the condition was cancer, and did not adopt any means of checking this grave conclusion. Mr Hunter said that he could only assure the court that that was not true. Asked if, supposing he had taken a specimen, he would have expected to find the same result as Dr Barringer, Mr Hunter replied, "In view of what has happened now, I think there would be no doubt, but I should still at that time have been quite dissatisfied with the report that came back from the pathologist, because I should have thought that I had taken a bit from a non-cancerous area."

Mr Justice Birkett: If you had been doubtful what this mass was, "It may be cancer," would you have taken a specimen then?

Mr Hunter: I was not doubtful.

Mr Justice Birkett: No. I quite understand what you are saying. "I was not doubtful. I was sure. With my experience and my examination I was sure, and I therefore decided not to take a specimen." I understand that perfectly. What I wanted to inquire was this. Assume for the purpose of the question that when you had made your examination and brought your experience to it, your mind was in a position of some hesitation. "This looks to me like cancer, but there are one or two elements which make me a little hesitant." Assume that state of mind. Would you have taken a sample then?

Mr Hunter: I would have taken a sample.

With regard to the diverticulum, Mr Hunter said that he agreed that it was there, all he could say was that his finger did not go into the opening because he thought the opening was closed by the swelling of the mucous membrane. The diverticulum was a secondary manifestation to the prostatic obstruction. He agreed that the procedures followed by Dr Barringer were ordinary and useful procedures carried out by some surgeons.

The real trouble was something different from what you had diagnosed?—No, I diagnosed a condition which was present, and on top of that was this other thing.

And you concluded that it was cancer?—I did, yes.

Merely on what you saw and what you felt?—That is correct.

In re-examination the question was put to Mr Hunter as to what steps he would have taken assuming that he had felt doubt about his diagnosis, and Mr Hunter replied:

"I think you would have to be very definitely in doubt, but I think myself that there are only two things that happen about it when you make a diagnosis of this kind. You say, having taken all your experience into consideration, 'This is a carcinoma,' on that side, and then, on the other side, 'I do not think this is a carcinoma, I am going to take a section.'"

In reply to a further question, he said that in serious doubt he would have had a microscopical examination made.

Two urological surgeons gave evidence in support of Mr Hunter, the nature of their evidence at certain points is indicated in the judgment.

### Judgment

Mr Justice Birkett delivered judgment on July 29. Dealing first with the case against Dr Gleed, he said that Dr Gleed

when first consulted made a tentative diagnosis of enlarged prostate and advised a further opinion. Thereafter he acted in accordance with the view of Mr Hunter whom he had called in. Mr Hunter had said that it was an approved practice of the medical profession for the surgeon to accept full responsibility for the diagnosis, and he accepted such responsibility. Two other urological surgeons who had been called for the defence agreed that this was the recognized practice. One of the points made against Dr Gleed was that in his examination before Mr Hunter was called in he did not use a cystoscope, but he said that he did not possess a cystoscope and knew no general practitioner who did. It was also suggested that after Mr Hunter had made his diagnosis of cancer Dr Gleed should have made an independent diagnosis, and was negligent not to have done so. The judge was unable to accept that view, Dr Gleed had acted in all that he did in accordance with the approved practice of the medical profession, and no negligence could be attributed to him. The case against Dr Gleed failed.

Wholly different considerations arose in the case of Mr Hunter. Everything here turned upon the mistaken diagnosis of cancer, for it was this alone which determined Mr Hunter not to remove the prostate and indeed to do nothing more. It was charged against Mr Hunter that he had not used a cystoscope, whereas this was the first thing that Dr Barringer, the American surgeon, had done. Dr Barringer had said that the steps which should have been taken to verify the diagnosis were a complete examination by means of the cystoscope—and there was no difficulty or danger in making such an examination—and through the open bladder, with a pathological examination of any questionable areas. This was clear and unambiguous evidence. Mr O'Sullivan had quoted from Rose and Carless's *Manual of Surgery*, 17th edition, of which Mr Hunter was joint editor, and there it was stated, "Of recent years the chief means of examining the interior of the bladder is the cystoscope", and again, "The diagnosis of a vesical tumour can only be made by the cystoscope, and by discovering fragments of its substance in the urine. Early cystoscopy is all-important," and yet again, "Cystoscopy is now used so constantly that it is needless to lay stress on its value." Mr Hunter had said that there were special reasons in this case why he considered it inadvisable to use a cystoscope, and one of the medical witnesses for the defence (Mr Arnold Ward) had said that there was nothing inconsistent with proper care in not using a cystoscope, while the other (Mr Julian Taylor) had said that on the occasion of Mr Hunter's first examination, when there was urinary retention, it would have been dangerous to have used a cystoscope, and on the second occasion there was nothing to suggest its use.

The next question was that of the biopsy. Ought Mr Hunter to have done what Mr Barringer did in this matter? Here Mr Justice Birkett read from a report in the *British Medical Journal* of July 10, 1948 (p. 85), of the meeting of the British Association of Urological Surgeons at which Mr T. J. D. Lane, of Dublin, speaking of what he first called an "uncommon" bladder condition simulating carcinoma, was reported as follows:

"Biopsy was essential for proof of the presence of cystitis cystica and to differentiate it from cystitis granulosa and follicularis on the one hand and from malignant disease on the other. The resemblance to cancer in some cases had to be seen to be believed. Although in his title Mr Lane had used the word 'uncommon,' he said in conclusion that the condition was probably not very uncommon. There was little doubt that, if biopsy were resorted to oftener, glandular and other forms of metaplasia would be found much more frequently."

Mr Hunter had said that he considered whether a portion should be taken for microscopical examination, but decided against it because he would have had to cut very deeply to get a suitable piece, and there was a possibility of going through the bladder and opening up spaces behind it to infection, also the wound would not heal and would leave an ulcer, while a scraping or superficial portion, avoiding deep cutting, would have been useless for his purpose. Mr Justice Birkett dealt at length with the evidence of the medical witnesses on this

<sup>1</sup> It is not every slip or mistake which imports negligence, and in applying the duty of care to the case of a surgeon it is peculiarly necessary to have regard to the different kinds of circumstances that may present themselves for urgent attention.—*Mahon v Osborne* (1939 2 K.B. p. 14).

## DIENŒSTROL OINTMENT B.D.H

The greater pituitary inhibiting activity and lower œstrogenic effect of dienœstrol (Journ Clin Endocrinol, October 1947, p 688) as compared with stilbœstrol render it especially useful for the treatment of menopausal disturbances in which the œstrogenic effect is comparatively undesirable. This applies to local application as well as to systemic administration and Dienœstrol Ointment B D H is of special value for the treatment of menopausal dermatoses. It is also recommended for the treatment of endocrine dermatoses at all ages when the maximum local effect is desired with the minimum effect on the uterus. Further information is available on request.

# DERIPHYLLIN

THEOPHYLLIN and DI-ETHANOLAMINE

indicated in

**Cardiac Decompensation, Oedema,  
Angina Pectoris and Cardiac Asthma**

Deriphyllin has a regulating action on water metabolism and influences the cardiac mechanism. By dilating the coronary vessels and relieving any coronary spasm which may be present an improved flow of blood through the heart-muscle is secured.

Deriphyllin is exceedingly well tolerated and may be given for a long time (chronic cardiac decompensation) without reaction occurring. Effect does not decrease after prolonged administration. Can be usefully combined with the organic mercurial diuretics. Not contra-indicated in renal disease.

Available in liquid form for oral use  
ampoules and suppositories.

Now also available in the form of capsules

**Deriphyllin-Strophanthin** is indicated for most cases of heart failure.

Available in the form of ampoules and  
suppositories.

*Literature and samples on request*

**CAMDEN CHEMICAL COMPANY LIMITED**

61, GRAY'S INN ROAD, LONDON, W.C.1

## Allaying Anxiety...

For economic and medical reasons, the doctor's advice is being increasingly sought on the subject of "PLANNED PARENTHOOD" and Birth Control, in its clinical aspect, is rapidly becoming a new branch of Medical Science.

## GYNOMIN

THE SCIENTIFICALLY BALANCED ANTISEPTIC  
AND DEODORANT CONTRACEPTIVE TABLET

GYNOMIN is included in the approved list of contraceptives issued by the Family Planning Association. Closely approaches the ideal and adequately fulfils physical and psychological requirements.

- 1 Spermicidally efficient and clean in application.
- 2 Non-irritant, non-greasy and harmless to health.
- 3 Keeps perfectly in all climates.

FORMULA Each tablet contains - Sodii Bicarb B.P. 0.14 gm.  
Acid Tart B.P. 0.122 gm. Sod-dichloro-p-sulphamida benz-  
zoate. 0.0128 gm. Perfume q.s. Excipient to 1.16 gm.

# A new approach to the relief of pain

TETRAETHYLAMMONIUM salts were found in 1945 to block the transmission of nerve impulses through the autonomic ganglia, and they have been employed diagnostically in selecting patients for sympathectomy suffering from peripheral vascular disease.

Tetraethylammonium Bromide may be used therapeutically to give relief from pain in peripheral vascular disorders, causalgia and post-herpetic neuralgia.

Injection of T.E.A.B.-Boots Supplied as a 10 per cent solution for intravenous or intramuscular injection — Boxes of 12 x 1 cc ampoules 8/1½, boxes of 12 x 5 cc ampoules 12/3½ (Prices net to the Medical Profession)

point, and mentioned Dr Barringer's statement that at the time in question there would have been no difficulty or danger in obtaining a section. The learned judge also quoted from Rose and Carless, under the heading "Tumours and Cysts," that "at present there is no certain means of diagnosis, except clinical, and the microscopical examination of a portion of the growth removed for the purpose."

The real question was whether Mr Hunter exercised the reasonable care required of him. A mere mistaken diagnosis would not of itself be evidence of negligence. It might be akin to the "slip" mentioned by Lord Justice Scott in *Mahon v Osborne*.<sup>1</sup> Certain things appeared to be quite clear: (1) the diagnosis was wrong, (2) the diagnosis was made on sight and touch alone, relying upon past experience, (3) the wall of the bladder gave the appearance of cancer for Mr Hunter to make his diagnosis and for Dr Barringer to have felt doubt about it. The recognized test in these circumstances, apart from the clinical, was by means of a biopsy, and the microscopical examination must be made when circumstances permitted.

Now I am clearly of the opinion in this case that Mr Hunter's duty to the plaintiff was to have made such a microscopical examination in the circumstances of this case if it was reasonably possible for it to be done having regard to all the considerations he must keep in mind. Dr Barringer said it could and ought to have been done. Mr Hunter and his witnesses said, for the reasons they gave, that it could not and that it ought not to have been done.

He regretted to have to come to the conclusion that he could not accept Mr Hunter's reasons as a justification for not taking a sample for microscopical examination. Dr Barringer took the sample when he thought the area might be cancer, and if Mr Hunter's reasons were to be accepted as against Dr Barringer's evidence the dilemma would arise that in any case of this kind, where cancer had been diagnosed, a biopsy would never be possible. He found therefore that there was negligence in not taking the sample for examination, and that Mr Hunter was lacking in the duty of reasonable care to the plaintiff in making the diagnosis he did in the way he did and doing nothing more to verify or check it, although the means of verification was available.

If the sample had been taken, as I think it was possible to take it on the evidence, the microscopical examination would have shown that there was no cancer, and, although Mr Hunter said it would have led him to the conclusion that he had not got a piece from the right place, so sure was he that his diagnosis was right, it may well be that he would have been shaken in his view and taken still further steps to verify his original diagnosis, which was, as I have said, of such infinite moment to the plaintiff.

On the matter of the cystoscope, he thought that on March 22 when Mr Hunter made his first examination and when the retention of urine was so marked Mr Hunter was justified in not using the cystoscope but before or on April 5 the date of the operation a cystoscopic examination should have been made for by then conditions had altered very greatly. He held the mistaken diagnosis to have been made because of the lack of reasonable care, particularly in the matter of the biopsy and the cystoscope.

His lordship then proceeded to assess the damages in view of the loss which the plaintiff had sustained and the expense to which he had been put. He came to the conclusion that in the aggregate these amounted to £6,300 and gave judgment for that amount against Mr Hunter, with costs.

In circular No 146/48 (dated Aug 25 1948) the Ministry of Health draws the attention of local authorities to the aftercare scheme which the National Association for Mental Health has been operating for the Board of Control and the Ministry. The scheme was designed to assist ex-Service men and women who had been discharged from hospital after treatment for psychotic and neurotic disorders. It is now apparent that these aftercare arrangements are becoming to be particularly associated with ex-Service men and are becoming a part of the civilian service for mental welfare which is now a function of local health authorities. In the future all such cases are to be referred by the regional hospital boards to the health authorities concerned and the latter can then provide any additional help or come to an arrangement with the National Association for Mental Health for the continuation of the work. The Ministry has asked local health authorities to let it know what they propose to do by Oct 1 so that the National Association can be informed in good time and call is likely to be made upon the services.

## Medical News

### Ninth International Congress on Industrial Medicine

The periods for formal registration by members have been arranged as follows: Sunday, Sept 12, from 10 a.m. to 5 p.m. at Church House, Great Smith Street, Westminster; Monday, Tuesday, and Wednesday, Sept 13, 14, and 15, from 9 a.m. to 10 a.m. and from 12.15 p.m. to 2.30 p.m. at Caxton Hall, Westminster. A number of social functions and demonstrations have been arranged for delegates during the week, and at the Royal College of Nursing a model of an Industrial Health Department has been erected and lecture demonstrations will be given in the Cowdray Hall of the Royal College of Nursing during the week. The Safety, Health, and Welfare Museum in Horseferry Road, Westminster, will be open during the week and a film unit will show films of industrial importance in the Museum Lecture Theatre. A Scientific Exhibition will also be open in the Bishop Partridge Hall, Church House, Great Smith Street, Westminster, when scientific apparatus and pathological specimens will be on view. A comprehensive programme of visits of technical interest has been arranged for the week following the Congress and full details of these are given in the Congress programme. The fee for the whole Congress is £3, but delegates wishing to attend only two sessions can do so on the payment of £1. The Secretary of the Congress is Dr Harold J. Davies, Room 501, Garden Court Wing, B.M.A. House, but during the week of the Congress all communications should be addressed to him at Room 16, Caxton Hall, Caxton Street, Westminster, S.W.1. From Sept 13-17, the following social functions have been arranged: Monday, Sept 13, 6.30 p.m., cocktail party in the Georgian Restaurant of Messrs Harrods, Ltd, Knightsbridge, London, S.W., arranged by the British Organizing Council and the Association of Industrial Medical Officers; Tuesday, Sept 14, 6 p.m., Government Reception at Lancaster House, St James's, London, S.W., when the Rt Hon George Isaacs, M.P., Minister of Labour and National Service, will receive the guests; Wednesday, Sept 15, 10.45 p.m., special performance of the film "Hamlet," at the invitation of the J. Arthur Rank Organization, at the Odeon Theatre, Leicester Square, London, W.C. The preliminary programme of the congress was published in the *Journal* of Aug 14 (p. 351).

### Chinese University President

Professor Cheer Shee nan, acting president of the National Central University, Nanking, and dean of the college of medicine, is visiting Britain under the auspices of the British Council until the end of October. He has been attending the Mental Health Congress in London and will afterwards make a study of recent advances in the field of internal medicine, particularly diseases of the cardiovascular system. He will also study hospital administration and teaching methods in medical and dental schools. Professor Cheer was one of the three medical delegates chosen to represent China at the World Health Organization Assembly in Geneva in June and July this year.

### Wills

Mr William Lloyd, formerly of London, W.1, left £32,773 13s. Dr Geoffrey Garland, of West Strand, Rottingdean, Sussex, left £43,187 7s. 4d.

## COMING EVENTS

### British Commonwealth Medical Council

An informal dinner party, arranged by the British Medical Association, will be held at the Café Royal, 68, Regent Street, London, W., on Tuesday, Sept 14, at 7 for 7.30 p.m., to meet the members of the British Commonwealth Medical Council on the occasion of its inaugural meeting.

### Dinner for London Insurance Practitioners

The Local Medical and Panel Committee for the County of London has arranged a dinner for London insurance practitioners to commemorate the termination of its period of office. The dinner will be held at the Café Royal, Regent Street, London, W., on Thursday, Sept 16 at 7 for 7.20 p.m. Tickets are 17s. 6d. each, exclusive of wines and applications for tickets should be made to the Secretary, London Local Medical Committee, Tavistock House (North), Tavistock Square, W.C.

### Society of Medical Officers of Health

The annual dinner of the Society of Medical Officers of Health will be held at Piccadilly Hotel, London W., on Thursday, Sept 16, at 6.45 for 7.25 p.m.

**Bengue Memorial Award Lecture**

Dr Paul Banzet (Paris) will deliver the Bengue Memorial Award Lecture on "The Surgical Treatment of Gastric Ulcers" at the Royal Institute of Public Health and Hygiene (28, Portland Place, London, W) on Wednesday, Sept 22, at 3 p.m. Admission is free without ticket, but readers are asked to inform the secretary of the institute in advance if they intend to be present at the lecture.

**Central Mediterranean Force Surgeons' and Anaesthetists' Dinner**

The annual dinner of the surgeons and anaesthetists who served in the Central Mediterranean Force will be held at Claridge's Hotel, Brook Street, London, W, on Thursday, Sept 23, at 7 for 7.45 p.m. Surgeons and anaesthetists may bring one guest and should apply for tickets to Professor H. W. Rodgers, OBE, FRCS, 4, University Square, Belfast, Northern Ireland.

**British Hospitals Contributory Schemes Association**

The Final Conference of the BHCSA will be held at Folkestone on Sept 30 to Oct 3, and the Annual General Meeting on Oct 1. Information may be obtained from the secretary, Royal London House, Queen Charlotte Street, Bristol, 1.

**SOCIETIES AND LECTURES****Tuesday**

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY 330, Gray's Inn Road, London, WC Sept 14, 5.15 p.m. *Dermatology as it Concerns the Ear, Nose, and Throat* by Dr A. C. Roxburgh. Illustrated by lantern slides.

**Thursday**

DREADNOUGHT SEAMEN'S HOSPITAL Greenwich, SE—Sept 16 3 p.m. Clinical demonstration by Dr R. Hartley.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE—At Anatomy Lecture Theatre, Edinburgh University, Sept 16, 4.30 p.m. *'Modern Trends in Anatomy'* by Professor J. C. Brasli.

SOCIETY OF MEDICAL OFFICERS OF HEALTH—At Piccadilly Hotel, London, W, Sept 16, 6.45 for 7.30 p.m. Annual Dinner.

**Friday**

BRITISH TUBERCULOSIS ASSOCIATION—At 26, Portland Place, London, W, Sept 17, 3.15 p.m. *Tuberculosis and Diabetes* by Drs R. D. Lawrence and Ian Mills. *Collapse Therapy and the Bronchus* by Dr L. E. Houghton.

MIDDLESEX COUNTY MEDICAL SOCIETY—At Central Middlesex Hospital, Acton Lane, NW, Sept 17, 4 p.m. Annual general meeting. Address *Diagnosis* by Mr Ivor Lewis.

**BIRTHS, MARRIAGES, AND DEATHS****BIRTHS**

Aldridge—On Aug 26 1948 to Hilda wife of Mr L. W. Aldridge FRCS a son.

Fox—On Aug 22 1948 at Elizabeth Garrett Anderson Maternity Home 40 Belsize Grove, London, to Margaret (nee Graham) wife of Dr John P. Fox of 103 Howberry Road, Stanmore, a son.

Harnes—On Sept 2 1948 at Queen Charlotte's Hospital to Betty wife of Dr W. A. Harnes, a son.

Hartley—On Aug 26 1948 at Oakvale Nursing Home, Sheffield, to Bee wife of Dr B. P. R. Hartley MBE, a second son.

Jack—On Aug 27 1948 at Elsie Inglis Maternity Hospital, Edinburgh, to Hilda wife of J. B. Jack FRFCS FRCS, a daughter.

Jones—On Sept 2 1948 at Okehampton, Devon, to Marjorie (nee Dobson) wife of Dr C. Gwynnda Jones, a son—John Richard.

Murphy—On Aug 28 1948 at King's College Hospital to Elizabeth wife of Mr C. I. Murphy FRCS, a daughter.

**MARRIAGE**

Stutt—Waite—On July 17 1948 at Holy Trinity Church, Claygate, John Charles, elder son of Rev and Mrs J. W. Stutt, 25 Strathmore Park, North Belfast, to Pamela, elder daughter of Mr and Mrs Bryan R. Waite, Hillcrest, Beaconsfield Road, Claygate.

**DEATHS**

Drysdale—On Aug 30 1948 at 11 Clarendon Terrace, Dundee, Campbell Westwood Drysdale, MB, ChB, aged 46.

French—At Nairobi, found dead from gunshot wounds in the head, Stanley Gay French FRCS, aged 40.

Gill—On Aug 30 1948 at North Staffordshire Royal Infirmary, Alexander Wilson Gill M.D. FRCP of The Limes, Birlston, Staffs, aged 69.

Kelly—On Aug 27 1948 at North Wingfield, Derbyshire, John Booth Kelly L.R.C.P. & S.I. and L.M.

Marrriott—On Aug 30 1948 Francis Keene Marrriott MC MRCS L.R.C.P. of Yoxford, Suffolk.

O'Driscoll—On Aug 29 1948 at Bon Secow Home, Cork, Patrick O'Driscoll MB BCh.

Ong Chong Keng—On Aug 31 1948 murdered, Ong Chong Keng MB BS Hong Kong.

Paterson—On Aug 28 1948 at 340 Lee High Road, London SE, Arthur Robert Paterson M.D. Major IMS, retired, aged 88.

Rashleigh—On Aug 29 1948 at Coves Cottage, St. Peter's in Thanet, Hugh George Rashleigh MRCS L.R.C.P. late of Chatham, near Canterbury, aged 72.

Schmidt—On Aug 21 1948 Peter Wolstadt Schmidt MB CMEd of 161 Hookstone Road, Harrogate, Yorks.

Stephen—On Sept 1 1948 at 97 Fitzwarren Street, Salford, Lancs, Leslie Dechmont Stephen MB ChBEd.

Wise—On Aug 30 1948 at 115 Greenhill, Hampstead, NW, Kenneth Stanton Wise MB BS, late Surgeon General, Trinidad, BWI, aged 67.

**EPIDEMIOLOGICAL NOTES****Typhoid at Greenock**

A sharp outbreak of typhoid fever has occurred in the Greenock, Port Glasgow, and Gourock areas of Clydeside, and 30 cases had been notified by Tuesday, Sept 7.

The first 3 cases were holiday-makers in Gourock who had crossed the Firth of Clyde to Kilcreggan, a favourite place for picnic parties, and there had taken water (unboiled) from a stream. The next batch of cases came from members of a church organization who, to the number of approximately 700, proceeded on an excursion to the same resort. Large numbers are known to have drunk unboiled water from the stream, and 24 cases have so far been reported in this group. The next 2 cases were Greenock youths who were camping at Kilcreggan. All these are primary cases, and it is expected that their number will increase in the next week or two.

So far the organism has not been discovered in the stream, but the bacteriological findings on samples taken at various points are awaited. No individual who drank water from the same source which had been boiled has been affected. It is known that drainage from a few dwellings reaches the stream above the point from which the water was taken. There is no history of typhoid fever in the locality. The one factor common to all cases, however, is the consumption of water from this particular stream, and the evidence is overwhelmingly in favour of this as the cause of the outbreak. The dates of the visits to the waterfall cover a long period, the first patient having been there on June 30. Most of the infections, however, date from July 31, when the party of about 700 spent the day near the stream and, owing to the hot weather, drank copiously at the waterfall. One recent patient lives in a hamlet a mile from the stream and definitely did not drink at the fall. Inquiries are continuing into this and other cases. Attention has also been given to other possibilities such as ice cream bought in a nearby village, and farm milk—so far with negative results.

Most of the patients are children or adolescents. The incubation period has been long, the average being about 20 days. The illness has been clinically serious, but up to the time of going to press no death has been recorded.

**Discussion of Table**

In England and Wales a decrease occurred in the notifications of measles 1,286, whooping cough 198, and scarlet fever 38; an increase was recorded for acute poliomyelitis 35 and diphtheria 10.

The largest decreases in the notifications of measles were Lancashire 236, Yorkshire West Riding 119, Surrey 103, and London 98. In contrast to the decreasing trend of whooping cough in the whole country, a rise of 87 was reported in London, the largest falls were Middlesex 48 and Yorkshire West Riding 48. Only small changes were recorded in the local returns of scarlet fever. The notifications of diphtheria, despite the slight rise, have continued for four weeks at the lowest level ever recorded. No changes of any size occurred in the local trends of diphtheria during the week.

A new outbreak of dysentery, affecting 12 persons, was notified from Cambridge MB during the week. The other large returns for dysentery were Lancashire 40 and London 10.

The incidence of acute poliomyelitis was almost doubled, the largest centres of infection were London 10 (Kensington 2, St. Pancras 2), Middlesex 10 (Wembley MB 4, Twickenham MB 2), Kent 9 (Chislehurst and Sidcup UD 2), Lancashire 8. Notifications have been widely scattered, with a tendency for most of the cases to occur in the densely populated areas. On the whole the situation this year appears to be one of high endemic incidence quite different in degree from that of last year but similar in distribution.

In Scotland only small changes were recorded in the notifications of infectious diseases. In Glasgow the notifications of dysentery increased from 25 to 44.

In Eire increases were recorded in the number of notifications of whooping-cough 59, scarlet fever 29, and diarrhoea and enteritis 17. An outbreak of whooping-cough affecting 38 persons was notified from Galway, Oughterard RD. The rise in the incidence of scarlet fever was contributed by Dublin CB. The rise in the notifications of diarrhoea and enteritis was due to isolated cases in several areas.

In Northern Ireland the notifications of measles decreased by 9 while an increase of 7 was recorded for scarlet fever.

**Week Ending August 28**

The notifications of infectious diseases in England and Wales during the week included scarlet fever 812, whooping cough 3162, diphtheria 123, measles 3774, acute pneumonia 240, cerebrospinal fever 29, acute poliomyelitis 70, dysentery 70, paratyphoid 17, and typhoid 12.

A—Monteggia's fracture-dislocation is the name applied to the combined injury of fracture of the upper part of the shaft of the ulna and dislocation of the head of the radius. Typically there is an anterior angulation at the site of the ulnar fracture and anterior displacement of the radial head. Exceptionally, the forearm deforms to the ulnar. The injury occurs in both children and adults. Treatment is difficult because the fragments

unstable after manipulative reduction, yet operative risks, particularly for the radial dislocation, increase the risk of complications. Most surgeons advise operative reduction of the fracture of the ulna, with internal fixation by means of a plate, a bone graft, or an intramedullary nail. At the same time the head of the radius is replaced by manipulation. A full-length arm plaster is applied with the elbow flexed to the right-angle, and immobilization is continued until union of the fracture is present. The success of this line of treatment may be impaired by the occurrence of certain well-recognized complications. First, attempts to replace the head of the radius by manipulation may fail, or redisplacement may occur after initial reduction. Although this difficulty can be overcome by operative reduction with suture of the orbicular ligament or by excision of the head of the radius, these procedures considerably increase the risk of ossification of the surrounding haematoma and are reluctantly undertaken only in cases in which the injury is recent. Secondly, there may be delayed union or non-union of the ulnar fracture, demanding further operative treatment and further prolonged immobilization. Thirdly, in spite of the most careful treatment, ossification of the haematoma around the elbow-joint is a not infrequent occurrence and leads to serious limitations of elbow movements.

#### Hormone Treatment of Mastitis

**Q**—What are the relative merits of oestrogens, progesterone and testosterone in the treatment of chronic mastitis? What is the recommended dosage of each?

**A**—The optimum and, in fact, the only logical treatment of chronic mastitis is testosterone if we subscribe to the generally accepted view that this condition is due to excessive stimulation of the breast tissue by an abnormally high level of oestrogens. If the dose of testosterone is large—e.g., 600 mg by implantation or 25 mg daily by injection—the function of the ovary is completely suppressed and the breasts tend to atrophy. Smaller doses, varying with individual cases, will produce a modifying but less absolute effect and without the disadvantage of producing hirsutism and virilism. These changes are produced by inhibition of the secretion of the pituitary gonadotrophic hormones. A more direct local action, antagonistic to oestrogens, appears to be produced by local injection of testosterone in the form of an ointment, some 50 mg a week or less being adequate. Oestrogens and progesterone are sometimes prescribed on the theory that before menstruation tension is felt in the breast region when the breast structure, ducts and acini respectively, are not completely developed. This may be the case in a small proportion of patients.

#### Incision of the Hymen

**Q**—What is the most suitable local analgesic for division of a tough hymen? How much should be used and at what point should it be injected? What is the best technique immediately and post-operatively?

**A**—A 1% solution of procaine could be used to infiltrate the posterior and lateral tissues of the introitus and lower vagina at the level of the attachment of the hymen, and incisions could then be made postero-laterally. If the indication is dyspareunia or apareunia, however, this operation is not recommended. Incision of the hymen alone gives unsatisfactory results, because in many cases the whole introitus rather than the hymen appears resistant and nearly always there is an important element of vaginismus, at any rate by the time the patient seeks advice. Moreover, the woman who suffers long-standing apareunia is usually so nervous and apprehensive that it is unwise to attempt any procedure under local analgesia.

Apareunia in recently married women without gross vaginismus is mainly due to ignorance, a little instruction and perhaps the daily use of graduated vaginal dilators by the patient herself for a few weeks is all that is required. When, however, the difficulty is long standing and vaginismus is present it is usually necessary to carry out a digital dilatation of the introitus and vagina (this involves stretching or tearing the hymen) under general anaesthesia. After this the patient is instructed in the use of vaginal dilators daily for three weeks. The object of these is not to dilate the vagina further but to allow the patient to convince herself that any previous obstruc-

tion to coitus has been removed and to restore her confidence. The tendency to muscle spasm persists for a time, but this can be overcome by leaving a large-size dilator in the vagina for 10 to 15 minutes. Relaxation of the pelvic floor muscles is also favoured by telling the woman to concentrate on forcibly abducting the thighs when she is lying in the dorsal position with the knees flexed.

#### Erythema Nodosum and Ringworm Infections

**Q**—Is erythema nodosum a recognized accompaniment of animal ringworm infections? A young farm labourer had animal ringworm affecting principally the forehead, and painful shins. The lesions on his shins were undoubtedly those of erythema nodosum.

**A**—Erythema nodosum is one of the recognized patterns of allergic reaction to ringworm infections—an 'ide' reaction, more common with the animal large-spore ringworms than with other types of infection.

#### Snoring

**Q**—A man aged 30 who is about to get married snores loudly. He sleeps with his mouth shut, he has no obvious clinical obstruction in the upper respiratory tract and he seems healthy. Is there a remedy?

**A**—Snoring is in most cases due to the tongue falling back during sleep. In the absence of nasal obstruction or disease the usual cause is sleeping on the back. An old and simple means of avoiding this is to strap a small hard object on the middle of the back, so that the sleeper turns for comfort on to his side. The causes and treatment of snoring were discussed by the Section of Laryngology of the Royal Society of Medicine last year, and a report of this discussion appeared in the *Journal* (1947, 2, 835).

## NOTES AND COMMENTS

**Embalming**—Dr P. W. HAMPTON (Onchan, Isle of Man) writes: Your correspondent (July 31, p. 279) who wishes for a simple method of embalming might be interested in the way in which it is done in the trans-Pacific emigrant trade. It is part of the contract that the body of a Chinese passenger dying *en voyage* shall be returned to the Celestial Empire for burial. A layer of ashes from the stove hole is spread at the bottom of the coffin and chloride of lime (chlorinated lime) is liberally sprinkled over this. The body is then laid on top and formalin (40% formaldehyde solution) is injected at various points: neck, right and left sides of chest, abdomen at three or four places, and both thighs. Formalin is then poured into the open mouth and sprinkled all over the body, then chloride of lime again, and finally the coffin is filled with ashes. A four-ounce syringe is used with a wide-bore needle, and a quart jugful of formalin is sufficient. Of course this method is impracticable if the relatives wish to view the body at the end of the voyage. I have embalmed seven Chinese on a voyage from British Columbia to Hong Kong and can vouch for the soundness of this method.

#### Corrections

Dr S. G. B. D. GRAY (London E17) writes: May I correct a numerical error in my letter on children's medicines (*Supplement* Aug 21, p. 91)? "Suspension sulphathiazolis" contains 2 grammes (= 4 tablets) per ounce (not 4 grammes as I stated).

In the article entitled "Modern Therapy of Benign Tertian Malaria" by Dr J. F. Monk in the *Journal* of June 26 there is a misprint at the foot of p. 1224. The dose of quinine in the quinine-pamaquin regime should be 10 gr., not 10 g.

#### A PRELIMINARY

1 In April, 1947, the Council of the British Medical Association appointed a special committee with the following terms of reference —

"To investigate and report on existing forms of group practice, including partnerships and other forms of collaboration between general practitioners, and to relate this and other experience to health centre development"

The membership was as follows —

G O Barber, M A, M B, B Ch (Great Dunmow)  
A Beauchamp, M B, Ch B (Birmingham)  
J W Bone, B Sc, M B, C M, LL D (Treasurer), (Luton)  
H Guy Dain, M D, F R C S, LL D (Chairman of Council), (Birmingham)  
P J Gibbons, M B, B Ch (Liverpool)  
A S Gough, M B, B S, F R C S (Watford)  
C F R Killick, M B, Ch B (Williton)  
Sir Hugh Lett, Bart., K C V O, C B E, D C L, M B, F R C S (President), (Richmond)  
G Lowe, F R C S Ed (Tiverton, Devon)  
\*H M C Macaulay, M D, D P H (London)  
G MacFeat, O B E, M B, C M (Douglas, Lanarkshire)  
J B Miller, M D, D P H, J P (Chairman of Representative Body), (Bishopbriggs)  
T W Morgan, M B, B S (Kingston-on-Thames)  
A E Porritt, C B E, M A., M Ch, F R C S (London)  
A T Rogers, M B, B S (Bromley)  
J A Scott, O B E, M D, D P H (London)  
H R Youngman, M A, M D, D A. (Cambridge)

#### Observers —

R O C Thomson, M B, Ch B, appointed by the Ministry of Health

Burnett Davis, M D, United States Public Health Service

Dr A Talbot Rogers was appointed Chairman and Dr A Beauchamp Deputy Chairman

On consideration of the Committee's report the Council reserved for further discussion certain aspects of the subject, including the future of the general practitioner, specialist services in health centres, group practice, and the adaptation of the health centre to rural conditions. These matters will be dealt with in the final form of the report. The present interim report is concerned with the conception of the health centre and the general problems arising from it, and is submitted for the information of the medical profession, local health authorities, local medical committees, executive councils, and others interested in the development of health centres

The interim report is based on a field survey of the present structure of general medical practice carried out by Dr J Revans, then one of the Association's assistant secretaries, with the guidance of a comprehensive questionnaire prepared by the Committee. The data obtained in the survey has been used to build up a narrative picture of the advantages and the shortcomings of present-day practice, and to base upon these findings, and upon the individual experience of its own members, suggestions for the future, with particular reference to the desirability of developing health centres

and to the types of centre which might prove advantageous in the differing conditions of practice in different areas of the country

The Council is indebted to all those general practitioners and Divisional Secretaries who co-operated in the field survey. Dr Revans received the fullest possible help from everyone he interviewed on his travels. In every area suggested for investigation by the Committee ready co-operation was forthcoming. In addition, far more doctors than were needed or could be visited in the available time sent in suggestions that their particular practices or areas merited investigation. It was therefore necessary to refuse some invitations that could only have taken Dr Revans to areas very similar to ones he had already studied. Invariably Dr Revans found the doctors he was able to visit most communicative. His difficulty soon became not to get the required information but rather to stop the discussion of the ways and methods of that particular practice going on too far into the night.

In submitting its report to the Council the Committee expressed its appreciation of the skilful and tactful way in which Dr Revans carried out his task. It also acknowledged its indebtedness to one of its members, Dr Youngman, for his valuable assistance in the preparation of its report.

## B THE PRESENT STRUCTURE OF GENERAL MEDICAL PRACTICE

### 2 The Field Survey

As was stated in the previous section, an investigation was undertaken of the present structure of medical practice as carried out by general practitioners. It was thought advisable to consider both single-handed and partnership practices in rural, suburban, and urban areas. In addition some less formal methods of collaboration between neighbouring practitioners (not amounting to partnership arrangements) were examined. The single-handed practice (though not specifically mentioned in the Committee's terms of reference) was studied for two chief reasons: first, to find out how many of the single-handed practitioners found this method of practice preferable and so intended to continue practising alone and how many intended later to take partners or assistants, and, secondly, because it was felt that there might be found in this type of practice some who had tried but given up partnership practice, and who might therefore be able to indicate some of the disadvantages of group practice.

The areas visited by Dr Revans in the course of his inquiry included industrial areas, rural and agricultural areas, the great cities and some of their suburban or dormitory areas, seaports, holiday resorts, and mining areas.

### 3 The General Practitioner and his Work

(a) *The Doctor-Patient Relationship* Nearly everybody in this country has one general practitioner whom he regards as his own personal doctor. With certain exceptions, which will be discussed later, it is true to say that whatever kind of medical help is needed, in health or in sickness, the first resort is to a general practitioner, and through him the whole health organization is brought into action as needed. This system was used as the basis of National Health Insurance in 1912, and it is an essential feature of the new health service.

A strong bond exists in many cases between individuals and their family doctors which at its best rises to the level of great confidence on the one hand, a high sense of responsibility on the other, and a true friendship. All the doctors interviewed in the Committee's investigation stressed the

importance of maintaining this personal bond between the patient and an individual doctor in future conditions of practice.

It was found that the doctor-patient relationship was strongest in rural areas and towns with a stable population. It was less strong in the dormitory suburbs of London, especially among the poorer classes. In the vicinity of the London teaching hospitals it was weak mainly because doctors' letters of introduction are not insisted on, it was apparent that in these areas there was a tendency to make direct use of the hospital whenever the patient was able to go to it.

#### (b) *The General Practitioner's Place of Work*

(i) *The Home* General practitioners have the unique advantage among doctors that they are constantly visiting the homes of their patients. This gives them a knowledge of the patient's surroundings and a personal contact without which medical advice and treatment are very gravely handicapped. The importance of this factor in considering any reorganization of medical work cannot be over-emphasized.

(ii) *The Surgery* The majority of general practitioners have surgeries which form part of their own houses. In some cases rooms of an ordinary residence have been adapted for the purpose, in others the surgery has been specially built. In many cases the surgery has been established for 100 years or more. Often each doctor of a partnership has a surgery at his own house. In some cases the partners use a joint surgery, and this may be at the residence of one of the doctors of the firm, in other cases the joint surgery is away from the houses of all the partners and has a resident caretaker.

Another arrangement is the "lock-up surgery" encountered in the poor districts of large cities, the owner may live far away and be unobtainable at night and may leave emergencies to be dealt with by his colleagues.

From the patient's point of view there are advantages in the surgery located at the doctor's residence in that he is readily found outside surgery hours. The surgery away from a doctor's house is equally convenient if there is a secretary or caretaker always in attendance.

To the doctor a surgery forming part of his residence is frequently an embarrassment. The convenience of living by his work is more than offset by the interference with home life. The majority of doctors' wives would prefer the home to be right away from the surgery. The irregularity of meals in a doctor's house, the constant interruption of family activities, and the disturbed nights are enough for any woman to endure without the extra work she cannot avoid if she lives in the building to which come all the patients and messages and telephone calls.

When a joint surgery is combined with the house of one partner he usually gets more than his share of the emergency work. This can only be partly remedied by such an arrangement as an on-call rota.

Some excellent surgery premises were visited during the field survey. The advantages of specially designed premises over adapted rooms were obvious at once. Without doubt the approach of the National Health Service has retarded the development of surgeries generally. Doctors have been reluctant to spend money on their premises before they know what future conditions are to be. The present difficulties of getting building and repairs done and the prohibitive cost have also prevented improvement.

(iii) *Nursing-homes and Hospitals* The shortages of housing accommodation and domestic and nursing help often make difficult the proper care at home of patients who are confined to bed. This applies both to the sick and to maternity work. It is one of the main causes of the overwhelming

demand for beds in hospitals, nursing-homes, and maternity homes. Many of these patients need institutional care solely for domestic reasons, all the medical attention they need being that of their family doctors. The beds available for treatment under the care of general practitioners are limited to the private nursing-homes and cottage hospitals, and, in a very few instances, municipal maternity homes. There are not nearly enough, and most of them are too expensive for the majority of patients. In some of the smaller homes the standard of nursing is open to criticism.

(c) *The General Practitioner's Equipment* The equipment usually possessed by general practitioners may be summarized in the following list—

*Literary* Textbooks, reference books, at least one professional journal

*Diagnostic* Examining couch, stethoscope, sphygmomanometer, reflex hammer, specula (aural, nasal, vaginal, rectal), headlamp or head mirror, ophthalmoscope, urine testing equipment, microscope, containers for transfer of blood and other specimens to pathological laboratory, scales and measure

*Therapeutic* Sterilizer, syringes for injection of drugs and for injection therapies, aural syringe, instruments for minor surgery, midwifery equipment, including that for the commoner difficulties, and Minnitt or other analgesia apparatus, anaesthetic apparatus consisting usually of equipment for "straight gas," open ether and thiopentone

When, as so often is the case, a practitioner has some special interest or part-time specialty, he, of course, possesses more elaborate equipment in connexion with it.

It may be mentioned here that there is a tendency for minor surgery to be transferred from the consulting-room to the hospital or nursing-home or, in some industrial towns where injuries are frequent, to special minor surgery centres. The equipment available there is more complete and constantly ready for use, and there is more help.

(d) *Surgery Hours and Appointments* Consulting hours are usually in the morning and evening, but there is a tendency to introduce an afternoon surgery in some parts of the country. The times chosen depend on local industrial conditions and transport facilities. The extent to which definite appointments are made varies greatly. Consideration shows that an efficient appointment system for all patients is impossible. General practitioners do not know who is intending to come and any attempt at prior arrangement would greatly increase the burden on the doctor or his wife. Patients often fail to keep appointments even when made for special purposes. It is impossible to forecast the time needed for a particular patient, one patient requires a short time for the writing of a certificate, the next one twenty minutes for a careful examination, another five for removing a foreign body from his eye. Moreover, emergency calls to go out, and the unceasing telephone, are no more in abeyance during surgery hours than they are at meal times.

(e) *Ancillary Help* The lay help in a general practice varies from none at all to a secretary and a dispenser. As a rule there is less help than might usefully be employed with economy of professional time. It is rare to find a trained nurse employed whole-time by a general practitioner. The shortage of domestic help has greatly increased the burdens of the doctor's wife.

(f) *The Range of Work Undertaken by General Practitioners* Every kind of medical need comes within the field of the general practitioner as the first doctor to make contact with the patient. For many cases he does everything that is necessary himself. For some he calls in the help of the various kinds of auxiliary workers such as nurses, physiotherapists, social workers, and others.

Some cases he refers to a specialist of one kind or another who helps with diagnosis or treatment or may have to take the case over altogether, as, for instance, into hospital for an operation. This does not end the interest of the family doctor in the patient, the specialist keeps in touch with the doctor and eventually returns the patient with details of his treatment and final advice.

The family doctor thus becomes the pivot of the health service. The privilege, already mentioned, of constantly visiting the homes of his patients leads to an understanding of their problems which gives him an advantage over any other practitioner. He has the personal and family history of each of his patients in his hands, he gets to know their inherited constitutions, their strong and weak points, their physical and psychological circumstances. He also becomes, through long acquaintance, their trusted friend. He is the only possible co-ordinating centre for all that is done for his patient by specialists, nurses, and others. He alone provides continuity. Any attention given without contact with him is apt to be inappropriate through incomplete knowledge of the case.

Midwifery, domiciliary and institutional, forms a regular part of the work of the majority of general practitioners. It often forms one of the strongest bonds in the relationship of the family doctor with his patients. Some practices have a tradition of close co-operation with the local midwives, the practitioners making full use of the local authority's arrangements for antenatal and post-natal care by the family doctor as well as holding themselves available if the midwife sends for medical aid.

The training of doctors in the care of babies and their dietetics has improved enormously during the past generation. Indeed, the teaching hospitals—always the pioneers of any new development—were the first to establish, for the purpose of training their students in a new subject, the special baby clinics which soon spread all over the country and kept a large proportion of this work out of the hands of family doctors. All the same, family doctors who seek it can get plenty of experience in infant welfare. In more than one practice visited in the field survey the majority of the mothers attended the firm's own baby-clinics.

(g) *The Partial Breakdown of the Family-Doctor System* In both town and country there are definite exceptions to the rule that the family doctor is the primary point of contact between the individual and the health services. Side by side with the general practitioner service the public makes direct use of the various kinds of special clinics which have been established everywhere by the local authorities in recent years, and of the health visitor service. These have no organized contact with the general practitioner, and their work overlaps with his considerably. It is needless to point out the inefficiencies that arise from a state of affairs in which advice and treatment are given to the same patient by different doctors and nurses at different times or even simultaneously without any co-operation between them. An account of general practice to-day would be incomplete without a statement of the way in which this situation arose, because it represents a partial breakdown of the family-doctor system, or a failure to adapt it to modern conditions.

Great advances have been made in recent years in the theory and practice of preventive medicine. As new advances were made, naturally those interested in public health as a whole were quick to appreciate their possibilities and to apply them in their care of the health of the community. The family doctors on the other hand, inevitably preoccupied with the individual, were slow in realizing the importance of preventive work and in educating their patients in it. Also the doctor's fee prevented people from seeking advice and supervision or early treatment for minor ailments when they

did not feel really ill. The solution was the establishment of free clinics with preventive functions, such as antenatal care of healthy mothers and guidance in the management of healthy babies. In the first place these were started by voluntary hospitals for the surrounding districts, and in many other places by voluntary committees with charitable funds. They soon proved so valuable that they were adopted universally by the official public health service and have undoubtedly been the chief and most effective source of health education available to the community. Now it is impossible to draw a line between preventive and therapeutic medicine, it was a natural development that the maternity and infant welfare centres and the school medical service and the health visitors tended increasingly to give advice and treatment for the disabilities and ailments they discovered. The more was this so because reference of patients to their family doctors for treatment was likely to involve the payment of fees. Also in many cases co-operation was prevented by a definite antagonism between the general practitioners and the clinics, which they regarded as encroachments on their preserves. It must be said, though, that many practitioners made no attempt to provide what they resented others providing in their place.

Some examples follow of the kind of incoordination that has resulted from the existence side by side of two unrelated but overlapping services, the general practitioners and the clinics —

(1) At most antenatal clinics the expectant mothers are examined by medical officers who never conduct a confinement, but, if the midwife needs to summon medical aid, she sends for a practitioner who has had no opportunity of examining the patient beforehand.

(2) A child is found by his school teacher to have impetigo and is sent to the Education Committee's minor ailments clinic for treatment. His mother is due to give birth to another child at home. The family doctor who is attending her knows nothing of this source of septic infection in the house, and no special precautions are taken to prevent contact, with the result that the mother runs a risk of contracting puerperal fever.

(3) Health visitors often visit in the course of their duty the homes of young babies and others who are being attended simultaneously by their family doctors. Here is a situation in which two agencies could be complementary and extremely helpful to one another and the patient were there any organized co-operation between them. Alas, there is not. In most areas there is only occasional communication, more often doctor and nurse overlap without knowing it, give apparently conflicting advice, confuse an anxious parent, and exasperate each other.

(4) Cases are often referred direct to specialist departments of hospitals by school medical officers, clinic doctors, or health visitors without any communication with the family doctor. This often deprives those dealing with the patient at the hospital of useful information as to history and constitution, with bad and occasionally disastrous results.

(5) Treatment in factory clinics in some instances is carried out without any reference to the family doctor. In such cases the industrial medical officer or the industrial nurse has no knowledge of the family history or home environment of the patient. Without such background of knowledge, treatment can never be efficient. Knowledge and observance of the ethical rules for industrial medical officers by them and their nurses would lead to much more efficient treatment of the patient.

(6) The clinic medical officers do no home visiting. Therefore if a patient (adult, child, or infant) attending a clinic needs medical attention between sessions, or becomes unfit to go outdoors, it is necessary to call in the general practitioner and "swap horses in mid-stream". An actual case is that of a child who was treated at a school clinic for some days for a gastrointestinal upset with a medicine containing full doses of belladonna. While under treatment she became more severely ill during the night, and a general practitioner was sent for. He also supplied a medicine which contained belladonna, not knowing that the child was already taking this drug. Next day

the child was found to be suffering from belladonna poisoning and had to be admitted to hospital.

It is plain that an incoordinated state of affairs has developed in which there is much overlapping and wastage of professional man-power—a wastage which is especially serious to-day in view of the great shortage of doctors and nurses.

#### 4 Ways of Organizing Medical Practice

For the sake of clarity this section is considered under four headings, namely, Single-handed Practice, Partnership Practice, Group Practice, and Forms of Collaboration between Practices, each of which is defined. It will be appreciated, however, that this division is not rigid and that they frequently merge into one another. For example, (1) in a partnership there is almost always some diversity of interests among the respective partners, these different interests are utilized in varying degrees for the division of the partnership's work, and the most highly organized form of this differentiation, in which most of the partners are general practitioner specialists holding hospital appointments, is a typical group practice. (2) What has been termed collaboration may be anything from an informal arrangement between doctors to be on call for each other to a system which unites the practices of a town into something like an organized service, little different from the patient's point of view from a partnership.

#### 5 Single-handed Practice

(a) *Definition* Single-handed practice is a general practice carried on by one medical practitioner.

(b) *Description* The doctor to whom this type of practice most appeals is an individualist. He is stimulated by full responsibility, and would feel hindered by such obligations as exist between partners. He claims that the doctor-patient relationship is seen at its best under these conditions. He would never fit into partnership practice as we know it to-day.

It was found during the survey, however, that many doctors who were working single-handed were not doing so from choice. They disliked isolation and saw advantages in co-operation, many of them would now have been in partnership practice but for the interruption of their plans by the war.

It should be remembered that single-handed practice will always continue in some rural areas where no other arrangement is practicable. It is not confined to such areas now, and there are many practitioners who prefer single handed practice but are not suited to country life.

(c) *Advantages* The greatest advantage of single handed practice is that it attracts into medicine the extremely valuable type of man described above. The quality of the work in a one-man practice is often very high.

The occasional causes of disruption of a partnership are, of course, avoided. Some doctors interviewed had formerly been in partnerships which had proved incompatible and were determined to remain independent for the future.

The knowledge that the financial reward for harder work will be wholly his own is an incentive to the single-handed man.

(d) *Disadvantages* When a practitioner is absent from his work there is a more serious break in the continuity of attendance on his patients if he is single-handed than there is if he has partners. If he is called to an emergency or a confinement during surgery hours the rest of his patients have to wait or be sent away. Absence on holiday necessitates the employment of a locum tenens who has no knowledge of the patients. For this reason the doctor does not take as long holidays as his colleagues in partnership practice. (This is especially true in country districts, where it is often said

**LIVER** *at meal times*

## *In a Palatable, Readily Acceptable Form.*

Proteolysed Liver A & H is prepared by a process which eliminates the nauseating flavour of raw liver. Its palatability has been further improved by its presentation in a paste form. It may be readily incorporated in the normal diet by its inclusion in soups or on toast, bread or dry biscuits.

In pernicious anæmia and other megalocytic anæmias, proteolysed liver has proved effective in cases which have failed to respond to extracts of liver in general use.

### MULTIS TERRIBILIS CAVETO MULTOS (AUSONIUS)

Those that are a cause of fear to many should themselves avoid crowds. In Rome, do as the Romans do. But in modern times crowds are as difficult to avoid as the virus of the common cold. 'Endrine' nasal compound provides a simple method of treating coryza and catarrh. It contains ephedrine which shrinks the engorged mucosa, whilst the oily base brings soothing relief to the inflamed membranes. Free breathing becomes possible and droplet infection is prevented.

### ENDRINE Nasal Compound

Formula: ephedrine 0.75% w/w, menthol 0.5% w/w, camphor 0.5% w/w, eucalyptol 0.5% w/w, oleum ricini 0.35% w/w, liq. paraffin q.s. to 100.

### CELLON LABORATORIES LTD.

*The following tested preparations are available for prompt delivery —*

#### CELETANE (REGD) — MEDICATED (LETHANE) HAIR OIL—N W F

The modern insecticide for eradication of head lice (Pediculosis Capitis), as employed by many Medical Officers of Health, etc.

#### BENZELIA (REGD)—BENZYL BENZOATE EMULSION—25%

A well established preparation for rapid eradication of scabies within 48 hours. Also supplied in form of vanishing cream.

#### OLEOCIDE (REGD)—OLEO SULPHONAMIDE

This valuable preparation is a marked advance in Sulphonamide Therapy. Ensures rapid relief of ulcers, impetigo and other streptococcal infections of the skin, first and second degree burns—broken or unbroken.

#### CELOZENE (REGD)—ANTISEPTIC

A powerful non toxic, non-irritant antiseptic of great value for wounds and cuts, having a Rideal Walker value of 40. A special grade can be supplied for sterilising instruments.

#### SKLEN (REGD)—PLASTIC BANDAGE REMOVER (NON-INFLAMMABLE)

A solution for dissolving adhesive of plastic bandages enabling easy removal of plaster and subsequent cleansing of adhesive remaining on the skin.

KINGSTON-ON-THAMES  
Kingston 1234 (7 lines)

that the patients so obstinately await their own doctor's return that a locum does not earn his keep) For the same reason it is difficult to take time away for postgraduate study, and when ill the single-handed doctor is apt to stay at work longer than is good for either his patients or himself When in his practice the single-handed practitioner is usually on call 24 hours a day and 7 days a week, arrangements with colleagues for a rota of week-end or night duty are uncommon outside a partnership, and again are open to the criticism that the substitute doctor may have no acquaintance with the absentee's patients

The single-handed practitioner does not enjoy the advantage and stimulus of daily consultation and discussion of cases with colleagues Assistance, such as the services of a second practitioner to administer an anaesthetic, is not so readily obtained as it is between partners, and is sometimes dispensed with to the patient's disadvantage

It is not infrequently observed that in old age a single-handed doctor has carried on too long, or with too big a list of patients, before retiring or curtailing his work Frequent indisposition, unfitness for night work, and even failing judgment may then cause his patients to receive bad service A senior partner is less likely to be in this position, because patients are much more ready to transfer to a junior partner whom they already know than they are to leave their doctor for one in another practice

(c) *Conclusions* The Council considers that in urban areas the disadvantages of single-handed practice outweigh its advantages Although there are many highly efficient and successful practitioners working single-handed, and some who could not work satisfactorily in any other way, the rapid advance of medicine has made the single-handed practitioner's position a difficult one But the Council would be opposed to a policy which rendered single-handed practice impossible.

## 6 Partnership Practice

(a) *Definition* Partnership practice is defined as a general practice carried on by two or more practitioners associated by a partnership bond

(b) *Description* As mentioned before, the definitions used in this account describe types which frequently merge imperceptibly into one another There are partnerships which are little more than single-handed practitioners with a financial connexion At the other extreme is the highly organized partnership based on a joint surgery providing its patients with a wide range of service by means of partial specialization Many of the benefits of partnership practice depend on the possession of a common place of work at which all the partners meet

Most of the following advantages were mentioned by one or more of the practitioners interviewed as their reasons for preferring partnership practice

(c) *Advantages* Partnership gives the opportunity of frequent consultation with one's colleagues and of sharing responsibility with them Two heads are better than one, and it is so easy to obtain a second opinion from a partner—especially when there is a communal surgery Co-operation with partners also produces a friendly competition which stimulates senior and junior partners alike to improve their standard of work and keep up to date Entering a partnership is a most helpful way for the novice to start in general practice, so much of which cannot be learnt until one is engaged in the work

A partnership often provides its patients with an increased range of service by partial differentiation of work between its members Medicine is such a wide subject nowadays that it is impossible for one man to retain more than an elementary knowledge of all its branches though he may go further in

one or two So in a partnership if one member is specially interested, say, in dermatology, another in paediatrics, another in psychiatry, another in anaesthesia, though all remain general practitioners and have their own patients, they can be of great help to one another by exchange of patients for special purposes Or again, often one or two members may carry most of the midwifery of a firm

A family as a whole is better provided for by a partnership than by a one-man practice For example, a child often will not go to the same doctor as his parents, or the doctor becomes associated with some unpleasant episode in the child's mind, so that a change is advantageous There is usually one of the firm who is acceptable, and the continuity of treatment of the family by one practice is thus not broken It is often found that adults, too, appreciate being able to change their doctor (sometimes temporarily for a special purpose) without taking the step of going outside the practice under whose care they have always been In this connexion, and in various other ways, it is advantageous for a partnership to include doctors of both sexes

It is a great advantage to the doctor and his patients for him to have partners to do his work during temporary absence, thus avoiding all the hazards of employing a locum-tenent who is known by neither the patients nor the absent principal This gives the doctor a sense of security against the risk of illness, it makes it easier to take good holidays and time away for postgraduate study, and to arrange a rota of off-duty times instead of being always on call Many doctors say a partnership is worth while for this reason alone

It was observed during the survey that the partnerships usually had more equipment than the single-handed doctors, and a better library of professional books They also, as a rule, spent more on their premises and on secretarial and dispensing assistance These facts make it questionable whether the pooling of expenses leaves a greater net income per head in a partnership, but there is no doubt that partnership gives financial security

It was a common report that the starting of a partnership had been so successful in increasing the work of the practice that after one or two years it became necessary to take on yet another partner A good partnership gets a reputation that attracts patients and commands well-qualified candidates for membership of the firm

The great majority of partnerships were terminated only by retirement, owing to age or illness This durability of partnership arrangements is proof that they generally give satisfaction both to patients and to doctors

Another occasional reason for a partner leaving a firm is retirement from general practice to become a full-time specialist

(d) *Disadvantages of Partnership Practice* Apart from retirements as above, the following list of "disadvantages" includes all the causes of disruption of partnerships recorded during the Committee's investigation

No partnership is successful in which there is incompatibility of personalities This is probably the commonest cause of break-up of a firm Careful choice of a prospective partner by all the members of the firm, preferably with a few months' probation, would seem to be most important

One kind of incompatibility arises from great inequality of age between partners It is inevitable that this inequality should exist periodically in the life of a partnership, it is likely to be more prominent in firms of two or three and less noticeable in the larger firms containing members of all ages

Another cause of failure of a partnership is a partner who does not carry his due share of work and responsibility There is sometimes difficulty in getting rid of a partner who proves undesirable in this or other ways Such situations

arise most frequently in partnerships that have been started without a proper agreement. The value of a partnership deed prepared by a lawyer experienced in this work has been proved again and again.

Sometimes a junior partner is dissatisfied with his financial share in the firm, quite apart from any question of the work being unequally divided. In his early days in general practice a junior partner's work is not as efficient as it will become later. He earns less than his seniors for a time, and it is fair for his share of the proceeds to be less. In the past, however, senior partners have often retained for too long a major share, part of which could only be regarded as continued payment by the junior partner for his place in the firm. Such inequality has been less common in recent years, many modern partnership deeds contain a clause providing for a periodical review of the earnings of the partners and revision of their shares.

The influence of wives is sometimes fatal to a partnership, and it is usually connected with the situation of consulting rooms at the residence of one or more of the doctors. Jealousies or disagreements may arise about the allocation of the doctors' work, or a wife may dislike the neighbourhood of her husband's practice for her own sake or that of her children and do all she can to get him to move away.

The patients of certain partnership practices complain that it is difficult to get attention regularly from one doctor, but this usually seems to be due to lack of proper organization. The average patient agrees readily that his doctor is entitled to be off duty at definite times, especially if he knows there will always be some member of the firm available for emergency. He is also willing to go to any partner for attention of a routine kind and for trivialities, but he appreciates himself the value of continuity of treatment, and for the more serious purposes rightly expects to be able to keep to the doctor of his choice.

A large partnership runs a certain risk of losing the personal touch with its patients, and needs to be on guard against the intrusion of an institutional atmosphere, for instance, a joint surgery should look like a suite of private rooms and as unlike a hospital out-patient department as possible.

(e) *Conclusions* The Council considers the advantages of partnership practice outweigh its disadvantages, it is difficult to conceive a type of general practice more suited to the needs of the present day than a partnership of doctors combining the fine traditions of the family doctor with a variety of interests and experience.

## 7 Group Practice

Group practice is a practice carried on by three or more practitioners in partnership, having a definite relationship with a hospital, providing general practitioner service for their patients, and also covering to a considerable extent the work which is more usually done by consultants and specialists not in general practice.

The Council will give a fuller account of group practice in its final report.

## 8 Forms of Collaboration between Practices

(a) *Definition* Collaboration is a system organized between the members of the various practices in an area with the object of ensuring continuous service to the public while enabling the majority of the doctors to be off duty at night and at week-ends, leaving one or more of their number on duty in rotation.

(b) *Description* The rota system has not been generally adopted, though it appears to be increasing, especially in the industrial areas. Even within some of the large partnerships visited no arrangements had been set up for a rotation of times on and off call. This is inefficient in that no doctor can

really remain constantly on call 24 hours a day, even if he is so nominally, and if no plan is made there will be times when no member of a firm or even no doctor in a town can be found.

The following are typical examples of collaboration —

(i) Night duty and week-end duty are shared among a group of doctors, one of the group is on duty each night in rotation and takes the night calls of all the practices concerned, similarly, week-ends are taken in rotation. In one example of this system there was an interesting clause in the agreement that permanent transfer by a patient to a doctor met on rota duty would not be accepted.

(ii) The "multiple five" type. The rota panel consists of a multiple of five. Each doctor is allotted one of the five nights from Monday to Friday and retains it as his night on duty, and week-ends from Saturday to Monday morning are taken in rotation. For example Dr A is always on call on Monday nights and takes one week-end in five. On Monday nights Drs B, C, D, and E exhibit a notice to say that Dr A is responsible for seeing all patients from 8 p.m. to 9 a.m. Only one of the five is away on holiday at a time. All police stations in the neighbourhood are furnished with a copy of the rota.

Rota arrangements appear to have the effect of reducing out-of-hours calls to a minimum, patients prefer to wait until their own doctor is available unless the matter is really urgent.

(c) *Conclusions* These forms of collaboration do not overcome the main difficulty of single-handed practice, lack of help in the day time, as described on page 110. They do, however, provide the single-handed doctor with a solution of the problem of giving his patients a 24-hour service. The patients get to know their doctor's deputies, though not to the same extent as in a partnership. The employment of a locum tenens for a holiday of any length is usually necessary. In the Council's view collaboration removes some of the disadvantages of single-handed practice but does not procure for patients or doctors the very positive advantages of partnership.

## C PLANNING FOR THE FUTURE

### 9 Summary of Existing Conditions

Having studied the facts of present-day practice organization as revealed by the field survey the Council's next task was to consider what should be the direction of development of general practice under the new National Health Service and how the best features of existing practice might be incorporated in any new system. It will be convenient first to summarize the bad and good points of the present system. The findings may be put under two headings.

#### (a) Defects of the Present System that must be Remedied

(i) The most serious defect is the arbitrary division of family medical practice into several compartments, represented by the various clinics and so-called general practice. This started with an attempt to separate preventive from therapeutic work, which is impossible, and has ended, in an attempt to separate ambulatory from domiciliary work, which is indefensible.

(ii) Many doctors work too much in isolation. The more solitary a general practitioner is, the harder it is for him to play his part under modern conditions. Medical officers of clinics, on the other hand, are handicapped by confinement to a too narrow field of work and lack of contact with their patients' homes.

(iii) Some doctors' surgeries are ill-suited to their purpose, few have ideal labour-saving premises or as much secretarial, dispensing, and nursing help as they could profitably use.

(iv) The care of patients in bed at home is often difficult through lack of room and the shortage of domestic and nursing help. This leads to many patients being admitted to hospitals on the ground of domestic difficulty and not because they need the

attention of a specialist or the full facilities of a hospital. They thus occupy beds which ought to be available for cases requiring specialist investigation and treatment.

(v) Even under perfect conditions the family doctor would have no easy life, but as things are to-day many are needlessly burdened by conditions that could be altered with advantage to the public as well as themselves. Examples are the surgery combined with the home, shortage of domestic and secretarial help, and lack of planned free time.

(vi) All the above factors lead in one way or another to waste of professional time which the nation could ill afford to pay for even if there were not a shortage of doctors.

*(b) Features of the Present System that must be Retained or Developed*

(i) The personal doctor-patient relationship, characteristic of existing general practice, takes first place. Derived from this are the conception of the family as the clinical unit and the position of the general practitioner as the co-ordinating figure from whom the whole of the health services radiate.

(ii) The intellectual stimulus of working in frequent contact and consultation with colleagues is a valuable factor in maintaining a high standard of medical practice.

(iii) Experience has shown that many of the chief benefits of partnership depend on the partners having a common place of work.

(iv) The variability and flexibility of practice to suit different conditions, the purely voluntary nature of partnerships, and the freedom of doctors to organize their work as they think best are features suited to the national character and largely responsible for the high standard of medical work in Great Britain, and should be preserved.

## 10 The Changes Needed

The Council is of opinion that, in any planned development of practice, organization should incorporate the following points:

*(a) The General Practitioner and the Work of Clinics* Some way must be found of uniting the work of family practice with that of the clinics. It is not enough to conduct infant welfare, venereal, and other clinics in the same premises or even to arrange in addition that the work of the clinics is conducted by general practitioners. Essentially, the work of the clinics is either specialist in character, in which case it should be undertaken by specialists at or in association with the hospital, or general practitioner in character, in which case it should be undertaken by general practitioners as part of their daily work. What is wanted is assimilation and not merely liaison.

*(b) The Grouping of Doctors into Family Practice Units* The Council is satisfied that the co-operation of general practitioners in groups with a partial differentiation of function is the most effective way for them to cover the whole field of family practice while preserving the personal doctor-patient relationship. It desires to emphasize that such groups are unlikely to be successful unless they are formed voluntarily. Attention is also drawn again to the experience of the profession that a legal agreement is the best way of ensuring the harmony and permanence of a partnership.

*(c) Improved Working Conditions and Help* Doctors, as the most highly trained and expensive members of the Health Service, should be provided with conditions of work and ancillary help which enable them to produce with the highest degree of efficiency the maximum output of the work for which they have been trained. Although this may involve a great expense such expenditure must be balanced against the alternative expense of training enough extra doctors to provide the man-hours that are now wasted on unproductive effort.

*(d) General Practitioner Beds in Hospitals* It is most desirable that there should be more institutional accommodation for patients confined to bed but not requiring specialist treatment. This applies both to normal maternity cases and to illness. There will be little chance of this for years to come, but wherever it does become possible consideration should be given to the provision of hospital beds where patients could be treated by their family doctors. Such accommodation would not require the

standard of staffing or equipment necessary in the ordinary wards of a hospital, the cost per bed would be considerably less. It has been mentioned that a proportion of specialist hospital beds is occupied now by patients who are in them for reasons of domestic difficulty rather than medical necessity, these beds would be released for their proper use by the provision of the general practitioner beds.

It is important that the general practice wards should be part of a general hospital unit, and they should be under the supervision of the hospital authority. This would be a safeguard against the bad features of some small private nursing-homes. Also the knowledge that his work was open to hospital supervision would give the practitioner a strong incentive to keep up its standard.

*(e) Diagnostic Facilities* If one advantage of contact between the general practitioner and hospital work can be singled out above the rest, it is that he is kept alive to the importance of early diagnosis. The Council emphasizes the need of easy access by general practitioners to diagnostic facilities especially in the fields of radiology and pathology. As the first line of defence in the health service he has the principal part to play here. Recognition of the earliest signs of disease and immediate application of appropriate treatment will reduce incapacity and mortality far more than reference to hospital after a loss of valuable time. In surgery it has become obvious that the mortality rate of acute emergencies, and for that matter many other cases depends much more on early diagnosis and hospitalization than on the capacity of the surgeon who operates. The time factor is all-important, and this depends entirely on the acuity of the general practitioner.

## 11 The Health Centre Concept

Consideration of the aims described in the first three paragraphs of the last section leads with little further reasoning to a definite conception. It is that of a well-equipped building housing a group of doctors who carry out in a co-ordinated way all the work at present done by general practitioners and clinic medical officers. The remainder of the section pictures these doctors as having an organized association with the work of the local hospital. The working place of such a group of doctors may be called a "health centre". This term has already been applied to buildings of varying types with varying functions, but the Council is of opinion that although the organization of each centre should be flexible and adapted to local conditions it should in general conform to certain basic principles and that the development of a system of health centres should proceed on certain lines of policy agreed by the medical profession.

A detailed description of the Council's concept of a health centre is given in the sections which follow. No doubt most of the health centres which are started in the near future will differ from this picture in various ways. Some features suggested by the Council may be much ahead of their time, others may have to be modified in the light of experience.

The Council would be completely opposed to a widespread imposition of a health centre system without consultation of the local profession. It is probably fortunate that for years yet health centres will exist only where there is enthusiasm and determination to try them out in spite of current difficulties. If these experiments prove their value further centres will be welcome by the time it is possible to build them.

## D HEALTH CENTRES

### 12 The Services to be Provided

*(a) The Minimum Range of Service* The Council does not consider that any improvement on present conditions would be gained by the provision of health centres housing general practitioner services alone, or local authority services alone. The centre should unite these two in a single well-co-ordinated service.

As well as this the centre should have its own staff of nurses and midwives, so that frequent consultation will co-ordinate the work of doctors and nurses attending the same cases or visiting the same households. In a recent essay competition for nurses a surprisingly large proportion of the essays received from district nurses complained of the difficulty encountered in nursing patients while having no regular personal contact with the doctor in charge of the case. Every centre should also take part in a programme of health education. Thus the minimum range of work recommended includes

- General medical service
- Care of mothers and young children
- Care of school children
- Vaccination and immunization
- Antenatal and post-natal examinations
- Health visiting
- Home nursing
- Health education

(b) *Specialist Services* The provision of specialist services in relation to health centres is under consideration and will be discussed in the final report

(c) *Dental Services* No doubt many health centres will house the dental services which it is the duty of the local health authority to provide for mothers and young children, and the school dental services. In many cases it would be advantageous to provide accommodation at the health centre for general dental services too, but the opinion of the dental profession should be sought on this and experiments conducted with its co-operation

(d) *Pharmaceutical Services* Different districts will require different arrangements. The existing extreme shortage of trained pharmacists will affect the question of providing a dispensary in a health centre, especially as at least two dispensers would be required to cover the necessary hours of work. In many cases the most efficient pharmaceutical service will be obtained from the chemists' shops in the district, especially if they adopt a rota system for work out of ordinary hours

(e) *Health Centres and Medical Education* Many medical schools are taking an interest in the possibility of medical students or new graduates gaining experience of general practice and social medicine in health centres under the guidance of experienced general practitioners. The Association's Report, *The Training of a Doctor*,\* draws attention to the defects of clinical training based entirely on specialist hospitals and the distorted view of medical practice derived by students. After considering the possibilities of general practitioners teaching clinical students either in the lecture-room or in the field, this Report comes to the conclusion that general practice should be regarded as a post-graduate subject. A recent letter by Professor J. A. Ryle† even suggests that a year's postgraduate service in a health centre might eventually be a condition of admission to the *Medical Register*

The Council agrees that the health centre could take a valuable part in medical education—as, indeed, every partnership does to-day when joined by a novice—but certain pitfalls must be avoided. One is the suggestion that a health centre should be established conveniently close to, or in, a teaching hospital for purposes of medical education and research in social medicine. This might or might not be the best site for giving most convenient service to the patients of the centre, it would almost certainly not give the best conditions for the work. The impersonal atmosphere of a modern hospital must at all costs be avoided in a health centre. A health centre will not teach students the right lessons unless it is situated,

designed, and run appropriately for its primary purpose, which is the provision of family medical service

Those practitioners at the health centre who undertake the teaching should be chosen mainly by the local medical committee. The Council suggests that there should be whole-time apprenticeships at the health centre for students or new graduates, not more in number than the medical staff. Even quite short appointments of this character would be more useful than longer periods of visiting the centre by larger numbers of students who were not in a position to feel themselves part of its organization

(f) *Health Centres and Education of the Public* This matter is under consideration and will be discussed in the final report

### 13 Professional Staff and Organization of its Work

(a) *The Medical and Nursing Staffs an Organic Unit* One method of professional staffing is for all the professional work of the centre, as described in the last section, to be carried out by a unified medical and nursing staff. The doctors (about six to eight to a centre) are all general practitioners, for simplicity masculine pronouns will be used in referring to them, but wherever possible centres should have doctors of both sexes. Each doctor has his own list of patients who have chosen him as their family doctor and in general come to see him or are attended in their homes by him. There is, however, some division of kinds of work between the doctors. Of a staff of eight, say, four do most of the antenatal and maternity work for their colleagues' patients as well as their own, four, not necessarily the same four, manage regular baby clinics for the whole centre. To minimize waiting, special times are allotted for antenatal work and baby clinics, and also for attention to school-children. One or two of the doctors do most of the minor surgery, one or two give anaesthetics for dentistry and minor operations and confinements, and so on

Another method is for each doctor working in the centre to undertake the full range of general practitioner work—antenatal and post-natal, baby clinics and attention to school children included. There is professional co-operation between them without division of labour

The range of work undertaken and the extent to which patients are exchanged by the staff for special services will vary in different health centres. The doctors co-operating in a health centre should be able to make whatever arrangements they choose for the division of work among them, just as an ordinary partnership does to-day, provided that as a unit they carry out all the services the centre has been established to provide

The nursing staff provides health visitors, home nurses, and midwives for the patients on the lists of the centre. These all work in close co-operation with the doctors, being in daily contact with them and able to report to and consult with them on any case as the occasion arises. They assist the doctors at antenatal sessions, baby clinics and minor operations. The doctors who do midwifery conduct home confinements with the midwives when required, the anaesthetists are available for confinements whether conducted by a midwife or another doctor

(b) *Self-Discipline of the Medical Staff* A doctor's work, so much of which is individual, personal, and confidential, cannot be carried out efficiently under close bureaucratic control. It is the Council's opinion that doctors working the National Health Service should be entrusted with the maximum of freedom in every aspect of their work. For this very reason it assumes that the doctors practising in the health centre will co-operate as an organized group, and would regard the renting of consulting-rooms by practitioners who remained independent of each other as definitely undesir

\* Butterworth 1948 7s 6d

† *British Medical Journal* 1948 1, 1003

able. Less outside control will be needed if the medical staff makes its own arrangements to ensure harmonious working. No doubt various methods will be tried, but it is at least worth considering whether the doctors in a health centre should not join in formal partnership by means of a legal agreement with all the usual clauses providing for settlement of disputes, illness, retirement, and so on. The possible causes of friction in a health centre staff are much the same as those that have been reported in the account of partnership practice, and it seems likely that the most successful preventive measures will be the same too.

Successful co-operation will not be possible unless the doctors are working together by mutual consent, no doctor should be compelled to work in a health centre.

The Council notes with satisfaction that the Ministry has agreed that all doctors in partnerships under the National Health Service Acts shall be free to choose new partners to fill vacancies, and assumes that this applies to the staff of a health centre. It considers the regulations affecting general practitioners should be identical for them all, whether working in health centres or not.

(c) *Distribution of Earnings of Medical Staff* The payment of the doctors will come from more than one source. For provision of general medical services under Part IV of the National Health Service Act, including maternity services, they will be paid by the executive council, for provision of services under Part III of the Act, at least some of them will be paid by the local health authority, for services under Part II, whether performed in hospital or at the centre, by the regional hospital board. Also they should be entitled to receive fees for private work on the same conditions as doctors practising outside health centres.

The Council foresees considerable difficulty in arranging for an equitable distribution of earnings. It considers the staff should be free to adopt any method it chooses, but suggests that all these salaries and fees should be pooled and, after payment of joint expenses such as the rent of consulting-rooms in the centre, distributed to the members of the staff in agreed shares, which should be revised at regular intervals to keep them as nearly as possible proportional to the work done by each partner. Again it seems that the best way of avoiding disagreement over the distribution of earnings would be to let it be controlled on some such lines as these by the financial clauses of a partnership deed.

#### 14 Administration and Lay Staff of Health Centres

(a) *An Administrative Committee* In the words of the Act the local health authority is to "provide, equip and maintain" the health centre. The Council considers that the administration of the centre should be in the hands of a joint Committee representing all the professional personnel (doctors, nurses, dentists, pharmacists) and the medical officer of health or his nominee. The duties of the local health authority would be those of a landlord letting accommodation to the doctors in respect of their work under Part IV of the Act, for the provision of which they would, of course, be under contract with the executive council. The health authority would, however, be the employer of the doctors in so far as they were serving under Part III of the Act. It would also be the whole-time employer of the nurses and the lay staff. The health authority should delegate to the Committee the selection of the lay staff subject to the approval of the authority.

(b) *Administrative Secretary and Lay Staff* The chairman of the medical committee should have a responsible role in the administration of the centre. The remaining lay staff consisting of secretarial assistants, reception and record clerks, telephone and caretaker and cleaners would number about ten.

The way in which the work of the lay staff is carried out is very important. The introduction of health centres will do more harm than good if they acquire an institutional atmosphere. At all costs the patient must continue to feel that he is making a private visit to the doctor who is a friend of his own choice. This will not be easy, in hospital out-patient departments it has been difficult to avoid the impersonal handling of patients, and in the public health clinics, too, the atmosphere has been anything but one of privacy.

(c) *The Handling of Records* must be discreet. There should be nothing but identification details on the outside of a patient's records. It is probably best that those of each doctor's patients should be kept in his own consulting room. If they are kept in a central file, on the patient's arrival at the centre they should be taken to his doctor's room by the receptionist or other member of the secretarial staff.

#### 15 The Health Centre Building

(a) *Site* The strategic placing of a health centre will be most important in the eyes of the public. However well placed it is, many patients will have farther to go to the doctor than before, for the simple reason that the doctors are gathered together in a group of six or more, whereas they were formerly scattered about in ones and twos.

Town planning should provide for the sites of health centres even when there is no immediate possibility of building them.

(b) *Population to be Served* The Council has considered the figures suggested by various planning bodies. It estimates that in urban areas eight doctors could serve a population of 25,000 at one health centre. This would cover a district with a radius of about one mile.

These data are intended for use in deciding the number and siting of health centres in a given area. The "district" of a health centre should not be rigidly defined, as this would seriously limit the public's choice of doctor, especially in an area served entirely by doctors working in health centres. The areas served by partnerships of doctors at present overlap freely, in the same way no person should be compelled to receive attention from the nearest health centre if he prefers to go further to get a doctor of his choice who is willing to accept him on his list.

(c) *The Building should be Designed for the Purpose* The architectural plan, decoration, and furnishing of the health centre are of great importance. They will have a permanent influence on the psychological atmosphere of the centre as well as on its material efficiency. One quite often finds that patients prefer the inadequate but homely surgery of a doctor's house to more modern premises precisely because it does not give the impression of being a particularly medical affair. The architect should bear this in mind.

Ideally all health centres should be new buildings, but under present conditions the use of prefabricated units or the adaptation of existing buildings cannot be excluded. Only cases in which a really good functional result is possible should be considered.

(d) *The Accommodation Required* The Council does not intend to include detailed plans in this report but gives the following list of the accommodation it considers should be included—

(i) *The Administrative Unit* should consist of entrance hall with seats, reception and record office, telephone switchboard and office for the administrative secretary.

(ii) *The Consulting Unit* should contain a suite for each general practitioner on the health centre staff. Each suite should contain a consulting-room, an examining room and a waiting-room. As a minimum there might be one waiting room for patients of two doctors, a large common waiting hall is to be avoided. The decorating, furnishing, and equipping of each doctor's rooms should be carried out to his own taste.

(iii) *A Minor Surgical Unit* may or may not be required, depending on the character of the area served and the availability of a hospital Out-Patient Theatre. When provided it should contain a theatre and sterilizing-room, a dressing room and a recovery room.

(iv) *The Dental Unit*. When provided this should consist of surgeries for the dentists, recovery room for the patients, and separate waiting-room.

(v) *Antenatal Unit*, including waiting-room, consulting room, and series of examination cubicles.

(vi) *Child Welfare Unit*, including waiting-room, weighing room, toddlers' nursery, consulting room, small isolation room, and milk sales room.

(vii) *A Separate School-children's Unit* would have certain advantages. Whether it is considered essential or not there seems no doubt that at present the education authority would demand separate accommodation for the school clinic.

(viii) *A Dispensary* may be required.

(ix) *A Common Room* should be available to the medical and nursing staff for consultation and discussion. The provision of considerable amenities here, including facilities for the preparation of light refreshments, would in the Council's opinion add to the practical efficiency of the centre's work.

(x) *A Large Room* for lectures and demonstrations will be needed for the development of a health education programme if this is to be based on the health centre. Designs have been proposed in which folding partitions make it possible to unite some of the waiting rooms for this purpose at hours when most of the consulting-rooms are not in use.

(xi) *Sleeping Accommodation* will be required at the centre if it is considered necessary for the doctor on night-call to stay there.

(xii) *Toilet Accommodation* for staff of each sex and for patients.

(xiii) *Accommodation for Caretakers*. In many cases it will be convenient to employ a resident couple for this work.

(xiv) *Storage Space* for professional and clerical materials.

(xv) *Parking-space*, sheltered, divided into separate parts for (1) perambulators, (2) cycles, (3) cars.

#### 16 The Adaptation of Health Centres to Rural Conditions

This matter is under consideration and will be discussed in the final report.

#### 17 The Council's Plan and the National Health Service Act

The Council has given some account of its views on the purpose, structure, and staffing of a health centre and on the place which such centres should take in the development of the country's health and medical services under the National Health Service Act, 1946. That Act envisages the health centre as an important feature of the future health organization and places on local health authorities the duty of providing centres. Section 21 reads

"(1) It shall be the duty of every local health authority to provide, equip, and maintain to the satisfaction of the Minister premises, which shall be called 'health centres,' at which facilities shall be available for all or any of the following purposes—

- (a) for the provision of general medical services under Part IV of this Act by medical practitioners
- (b) for the provision of general dental services under Part IV of this Act by dental practitioners
- (c) for the provision of pharmaceutical services under Part IV of this Act by registered pharmacists
- (d) for the provision or organization of any of the services which the local health authority are required or empowered to provide
- (e) for the provision of the services of specialists or other services provided for out-patients under Part II of this Act, or

(f) for the exercise of the powers conferred on the health authority by section one hundred and seventy-one of the Public Health Act, 1936, or section two and ninety-eight of the Public Health (London) Act, 1936 for the publication of information on questions relating to health or disease, and for the delivery of lectures and the display of pictures or cinematograph films in which such questions are dealt with.

(2) A local health authority shall to the satisfaction of the Minister provide staff for any health centre provided by them.

Provided that a local health authority shall not employ medical or dental practitioners at health centres for the purpose of providing general medical services or general dental services under Part IV of this Act."

The latitude for development allowed by this provision of the Act makes it essential for the medical profession to see that health centres develop in accordance with the best interests of the public and with professional traditions and ideals, as has been suggested in the Council's report. The need for watchfulness has, indeed, already been demonstrated, for it is apparent from some of the local authorities' plans that their ideas of health centres do not correspond with the Council's recommendations and will not lead to the integration of clinic and family medical practice. The Council welcomes, however, the references to this subject in Circular 118/47 of the Ministry of Health, under the headings "Care of Mothers and Young Children" and "Health Visitors."

In the next section the Council discusses the need for adequate experiment before any one type of health centre is universally adopted. It is desirable that the medical staff of a health centre should have a corporate existence by some such means as a partnership agreement. Administrative relationships in a health centre will of necessity be complicated, and the existence of a partnership agreement would at least simplify the internal relationships of the staff and allow for wide variation and experiment in the distribution of the work.

#### 18 Proposals for Experimental Health Centres

(a) *Experimentation is Urgent*. The Council regrets the conditions which necessitated the issue of Circular 3/48 by the Minister of Health, in which local health authorities are discouraged from submitting any proposals for the immediate provision of health centres. The recent circular\* in which this position is somewhat modified is welcomed. While appreciating that there is no possibility of their general provision for some years to come, the Council urges that wherever it can be done experimental health centres should now be set up for the purpose of observing them in action and studying their effect on the efficiency of the health services. Circular 3/48 mentions the need for intensive research and thought about design, the Council and other bodies have done a great deal of this and the time is ripe for actual experiment. There are new towns and large housing estates being constructed in which some kind of accommodation for the health services will have to be built, in these it would seem an actual economy to build health centres in the most convenient sites instead of separate premises for the doctors' surgeries and the local authority services.

(b) *Existing Proposals and their Possible Development*. In the plans for health centres prepared by many local authorities the centre is simply a building housing a communal surgery for general practitioners side by side with accommodation for the clinics, the two parts continuing as at present to work without any organic connexion and with

\* Ministry of Health letter dated April 13, 1948, addressed to Major Local Authorities on Health Centres.

separate medical staffs. This plan goes only a little way towards the realization of the Council's ideal, though it is at least a start in the right direction. Their proximity will make it easier for the members of the two parts to meet, air their differences, discuss their problems, and begin to co-operate with each other over individual cases. As time goes on, it is to be hoped, there will be gradual integration of the two staffs into a family-practice unit of one kind or another, not necessarily on the exact lines which at present seem best to the Council. There is plenty of scope for extremely interesting experiment, very likely this will lead to the development of various types of health centres suited to the condition of different parts of the country.

(c) *Council's Proposal for More Advanced Experiments* The Council earnestly hopes that it will be possible in some places to make experiments in which the system of staffing described in Sections 12 and 13 of this report is tried from the start. It realizes this would have to be done without prejudicing the rights of the existing medical officers of clinics, but it is encouraged to believe from Circular 118/47 that this is not impossible. It is suggested that in some cases this problem could be solved by such medical officers being willing to co-operate in the experimental health centre by undertaking a share of the general practice and continuing with their special work on a part-time basis. Experimentation of this kind would in some ways be easier in a new or growing urban area, but it would also have a special interest if carried out among an old-established population.

(d) *The Initiation of a Health Centre* The first requirement for a successful experiment is enthusiasm on the part of those who would take part in it. The Council is informed that there are many groups of doctors in various parts of the country who would like to start health centre practices. In most of these cases there will be no possibility of providing new buildings in the near future, but it is quite possible that the doctors themselves may be able to assist in finding premises capable of efficient adaptation.

Whoever takes the first step, the stage of informal discussions should include the general practitioners and the clinic medical officers who are interested, the medical officer of health, and the local medical committee. The official initiative will have to come from the local health authority, which will no doubt consult with the executive council before taking action. Formal proposals will have to be published and submitted to all interested bodies at the same time as they are sent to the Ministry, and after any modifications found necessary the Ministry will give its approval.

All this machinery will undoubtedly move very slowly, so it is all the more important to get it in motion as soon as possible. The number of projects which any local authority and the Ministry of Health could approve will be limited by the amount of conversion required and, therefore, by the amount of material to be used.

(e) *Experiment in the Absence of a Building* In areas where it is impossible to provide any premises for a health centre it should still be possible to experiment with the health centre method to some extent. In fact it is possible that such experiments might lead to the evolution of an alternative to the health centre. It is possible to conceive of a close functional link between the general medical services and the public health services without any physical link in common premises, but at present the Council's opinion is that there are so many advantages depending on the physical contact that with it the evolution of a completely integrated service would go further.

A group of doctors could combine in an organized partnership with partial differentiation of function as described above,

the medical officers of the local health authority clinics, including the school clinic, being included in the group. Close liaison should be established with the nursing services, or preferably a group of midwives and nurses should be seconded by the local health authority to work with the doctors' group as a unit. A minimum physical link which would be essential to co-ordinate the work of this unit would be a central office to handle its correspondence and telephone connexions.

## 19 Conclusion

The Council, having reviewed the present conditions of general practice in this country, is satisfied that the most satisfactory form of practice at present and in the immediate future is partnership practice from a common surgery. It believes that the logical future development will be the provision of specially designed health centres from which both general practitioner and the present local authority services can be provided. Widespread development of such centres cannot, and should not, be commenced without experimental trial of different types of health centre in varying areas. Early experiment is advisable and prototypes should now be designed, built, and put into commission. A central committee should be established without delay, to offer guidance during this experimental period and to collect information of the results achieved.

## AUSTRALASIAN MEDICAL CONGRESS

### SIXTH SESSION

The Sixth Session of the Australasian Medical Congress of the British Medical Association was held from Aug 15 to 21 at Perth, the capital city of Western Australia. Over 500 medical men attended, of whom nearly one-half were practitioners in the home State. His Excellency the Lieutenant-Governor of Western Australia, Sir James Mitchell, was patron and opened the congress at the inaugural meeting in the Winthrop Hall.

The President, Dr McWhae, then delivered his address on "The Medical Profession of Australia and the War". After acknowledging his indebtedness for the detailed facts to Major-General S R Burston, Director-General of Medical Services of the Australian Imperial Force and Army during the war, he described how the profession was administered in wartime in order to provide for the needs of the Services and the civil population. One-third of the profession had served with the Armed Forces. By 1943-4 the Australian Army Medical Corps included 2,500 doctors, 3,500 nurses, and over 26,000 others, and it provided 35,000 hospital beds in Australia and in the operational areas, as well as 13,000 beds in casualty clearing stations and convalescent depots. The completely transportable mobile field hospitals and the pioneering of air carriage of casualties were placed to the credit of the Royal Australian Air Force Medical Service.

The President then drew attention to the post-war provision of overseas fellowships of the Nuffield and Carnegie Foundations and of the Carnegie Trust, and also to the Gordon Craig travelling scholarships. The total value was approximately £60,000, and between forty and fifty medical officers had already benefited. The Armed Forces and the community had been well and faithfully served by the doctors during the most difficult and fateful years Australia had ever known.

"Pulmonary Tuberculosis" was the subject discussed at the plenary session and various speakers considered such topics as control and preventive measures, treatment, sociological implications, radiological limitations, and clinical and laboratory methods. At the conclusion the Congress decided to support the formation of a voluntary body whose membership should be nation-wide to promote and co-ordinate anti-tuberculosis activities. Later in the week measures were taken to establish the National Tuberculosis Association of Australia. Sir Henry Simpson Newland was elected president and Dr D R W Cowan, of Adelaide, honorary secretary.

The Congress Lecture—on "Virus Disease and its Partial Conquest"—was delivered in the Winthrop Hall on Aug 18 by Professor F M Burnet, F R S, Professor of Experimental Medicine at the University of Melbourne and Director of the Walter and Eliza Hall Institute of Medical Research. He gave a lucid exposition in non-technical language and showed illustrations of the structure of virus bodies and swarms of them in action disintegrating bacteria. Afterwards the honorary degree of Doctor of Science was conferred on Professor Burnet, Sir Henry Simpson Newland (President of the Federal Council of the British Medical Association in Australia), and on two visitors from abroad—Professor James C Spence, Professor of Child Health at the University of Durham, and Professor F B Walsh, Professor of Ophthalmology at the Johns Hopkins Medical School, Baltimore.

The Congress conducted its scientific work in fourteen sections, meeting alone or in appropriate combinations. Reports of the proceedings will appear in the *Medical Journal of Australia*, there were 150 original opening contributions. Professor Spence contributed to the symposium on tuberculosis at the plenary session, made two addresses in the Section of Paediatrics, and entered into several of the discussions. Professor Frank B Walsh addressed a combined meeting of the Section of Ophthalmology with that of Neurology and Psychiatry on Aug 17, and a combined meeting of those sections with that of Medicine on "Myasthenia Gravis." The Section of Medicine held symposiums on "Ulcerative Colitis" (with the Section of Surgery), on "Hepatic Disease" (with the Section of Pathology, Bacteriology, Biochemistry, and Experimental Medicine), and on "Rheumatic Fever," and it was decided to advocate compulsory notification of rheumatic affections to the State authorities in order to obtain reliable information on which to base future plans. Hobbies and scientific and trade exhibitions were arranged, and provided much to interest the members of the Congress.

Visiting members were accorded a civic reception and luncheon, and the Congress dinner was attended by 300 members including all the visitors. Dr and Mrs McWhae held a reception and also gave a special dinner-party. The Western Australian Branch of the British Medical Association held a magnificent Congress ball.

The previous session was held at Adelaide in 1937, and the war intervened to postpone the one at Perth for nine years. It has been decided to hold the Seventh Session at Brisbane in 1950. Dr H M Trethowan, the Honorary General Secretary, is to be warmly congratulated on the success of the occasion.

## SPECTACLES FOR SCHOOL-CHILDREN

In a recent circular (Administrative Memorandum No 294) the Ministry of Education has told local education authorities how the supplementary ophthalmic services can be used for school-children. If the oculist selected by the authority is on the ophthalmic list, he will receive payment from the executive council. If a full-time medical officer of the authority is placed on the list, the remuneration received from the executive council should be handed over to the authority. (It should be noted that the fee payable for refractions undertaken at school clinic sessions is being reconsidered.)

The supply of glasses will be undertaken by ophthalmic or dispensing opticians on the ophthalmic list on presentation by the parent of the appropriate form (i.e., the prescription form or the form giving authority to repair or replace glasses). Education authorities will be charged by executive councils only when replacement or repair of spectacles is due to lack of care on the part of the child or parent. A charge will be payable by the parent, however, if glasses of a more expensive type are supplied than those ordinarily prescribed for this service.

Since there is to be freedom of choice of optician, the contracts which some authorities have with selected opticians, including in some cases arrangements for the selected optician to attend at the school clinic, cannot be continued. Detailed instructions about the method of completing the various forms are given in the memorandum.

## National Health Service News

### Ophthalmic Prescriptions

The method of writing an ophthalmic prescription generally accepted in this country and in the United States is

Right Eye	Sphere	Cylinder
Left Eye	Sphere	Cylinder

A large firm of optical manufacturers points out that some doctors now practising in this country write prescriptions in the reverse way—the cylinder written first instead of the sphere, and the left eye first instead of the right. In many cases these prescriptions are passed on to manufacturers whose staffs are trained in the conventional way of reading them, with the result that a large number of returns are incurred which could be avoided if all doctors adhered to the normal practice.

### Fees for Anaesthetists under Maternity Medical Services

Medical practitioners called in by midwives to give anaesthetics are paid in accordance with the Medical Practitioners (Fees) (No 2) Regulations, 1948—i.e., £1 15s plus the usual mileage fee of the district (with a limit of one mileage fee for one journey). The Minister of Health has decided that they shall be paid on the same basis if they are called in by general practitioner obstetricians or general practitioners providing maternity medical services for patients on their lists.

## HEARD AT HEADQUARTERS

### Gardens

Though the English are not often credited with great ability in the visual arts, there is at least one at which we have always excelled—filling odd patches, covering fences and walls, edging spacious lawns with beautiful flowers. Gardening is indeed the "popular" art of England, as folk-dancing or wood carving are elsewhere. Our temperate climate, though we often grumble at its vagaries, is one of the most perfect in the world for gardening and enables us to grow with a little trouble plants from the ends of the earth—dahlias from Mexico, primulas from the Far East, gentians from the Swiss Alps, nemesias from South Africa, and lilies from the Himalayas. The Ministry of Health is therefore to be congratulated on the publication of an illustrated booklet entitled *Our Gardens* (HMSO 1s) to help us, in the words of Mr Bevan, who contributes a foreword, 'to maintain in the surroundings and the settings of our homes that tradition of good gardening of which our country has always been proud. Nor is the town dweller forgotten, there are suggestions for window boxes and a climber such as the purple Clematis will grow from a small plot of earth to decorate an ugly wall. A copy of *Our Gardens* has been sent to all housing authorities with the request that it be brought to the notice of council tenants. No doubt their well-being as well as their pleasure will be enhanced if they carry out some of its suggestions.'

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non County Borough Councils*—Dartford, Radcliffe (limited to future appointments), Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton-le Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley

## Correspondence

### Pharmaceutical Services for All

SIR—I write to support Dr Lewis G Glovers proposal (*Supplement Aug 28 p 96*) that all registered medical practitioners irrespective of the branch of medicine in which they are engaged and of whether they are in the National Health Service or not should be allowed to prescribe on NHS forms and to obtain pharmaceutical services free of charge for their patients, all of whom are now automatically "in the service" and therefore entitled to this service.

I am myself engaged in clinical pathology. In this capacity my department carries out work for patients covered by the service but I myself am not a part of the Service. I am an employed person, and therefore have to make my weekly payments. I have placed myself my wife and my children on the NHS list of the general practitioner friend who has kindly looked after the family for some years, but the personal relationship between us remains unchanged. It is however a nuisance both to him and to myself if, every time a member of the family wants something from the chemist, I must call on him to provide a prescription. He has more than enough writing to do nowadays but I object strongly to paying the chemist myself when I already have to make a weekly payment towards his services—I am etc.,

Essex Surrey

GERALD OLLERENSHAW

### Scramble for Heads

SIR—If the distasteful scramble for heads is to be prevented the number of NHS patients on doctors' lists must be limited, also the *per capita* payment must be adequate. Given these two conditions then an adequate and fair and just service would be possible. For the first 1 000 patients on a doctor's list of NHS the payment should be 50s per head, for the second 1 000 patients it should be 40s per head, and for the next 500 patients it should be 20s a head.

Two thousand five hundred patients should be the maximum number allowed for any doctor in a single handed practice. For partnerships it should also be the maximum number allowed to each partner—i.e., 2 500. There is a mistaken idea among country doctors that town doctors will have lists of 4 000 people. This is quite wrong, with the exception of those in industrial slum areas. I think that the truth is that under the old NHI scheme both country and town practices had about 1 000 patients and under the new NHS scheme these numbers will be about double—i.e., 2 000. No man can cope properly with more than 2 500 potential patients. If the lists are not limited as I suggest the NHS will break down, and on the other hand work will be badly done. Most doctors will have to employ secretaries to cope with the increased clerical work entailed by the NHS. I invite the Minister of Health to come and see for himself how the practice is run—I am etc.

Southridge Works

F W CHEESE

### A Salaried Service

SIR—Under the National Health Service we now have doctors in some places faced with a considerable drop in their incomes, and in other places an increase of income with an intolerable burden of work. A proportion of the former will probably be forced to migrate from their present homes by economic sanctions.

Surely a health service with an adequate salary and reasonable conditions of work for all doctors and fair treatment for all patients would have been better. Further it is preferable that direction should rather be by a committee than by economics though no doubt the end result will be much the same. Under the present capitation system the average general practitioner is faced with a progressive reduction of income as the number of those in general practice increase, and thus will be forced into the under-doctoring areas.

I consider that the leaders of the profession have shown an incompensable lack of foresight and even common sense. They have attempted to continue the former conditions of

medical practice in a changing world, these were finished when it was agreed the service should cover 100% of the population. They have not been practical and have thought only of certain alleged principles or catchwords such as 'choice of doctor' and 'choice of patient'.

I do think it is shameful that these leaders should have agreed to and even urged on the Minister to make regulations which will put financial stress on some of their colleagues through no fault of their own. The situation would be eased if the basic salary was universal and raised considerably.

I personally would be glad to accept an offer of an adequate salary and reasonable conditions of work from the Minister at any time and to give up in return any right to private practice. I would then be able to attend to all my patients having regard only to their medical needs. I believe there are many more who think as I do and are disappointed with the present health service.

What I want to see is a service which encourages "the practice of medicine" and not just "the counting of heads" and, secondly co-operation among, and not competition between doctors—I am, etc.,

Bath

ROBERT J K FLEMING

### Certification

SIR—Would you allow me to register a protest against the supplementary certificate of the National Health Service? I am apparently expected to certify that I have examined some person unnamed and found him or her unfit for work. As far as I am aware this is a new departure in medical practice, and a highly undesirable one, which might be put to some quite unforeseen use in the hands of unscrupulous people—I am, etc.

Preston

J R EATOUGH

\*\* The Minister issued the following statement to executive councils on July 28. *Supplementary Certificate—Form Med 5*. By a printing error, the line was left out for the doctor to enter the patient's name on this certificate. The omission will be rectified when the form is reprinted. In the meantime, the Executive Council should, when opportunity offers, ask the doctors in their area to insert the patient's name at the top of the form before issuing the certificate.—Ed, B M J

### Crocodile Tears

SIR—'When I hear of people "suffering" when I hear talk of this kind, I stop before I either express or feel compassion to ascertain who and what the sufferers are.' Thus the abusive, hot-headed pre-socialist William Cobbett. Do our socialists apply even that rule before giving utterance in similar circumstances? Nothing is easier to produce than a torrent of passion and eloquence in defence of the imaginary wrongs of the sick and suffering yet Mr Bevan and one or two socialist women thought this a fitting manner in which to inaugurate the National Health Service. But crocodile tears of this kind are only drops in the ocean beside the genuine but unwept tears of thousands of doctors every day for the melancholy sufferings of many of their patients. May one therefore, express the hope that this may be the last of such diatribes on the subject of suffering from people who do not know to those who do.

A dignified restraint of utterance, tolerance, and a refusal to burst into a raging flame when some comparatively trivial rules have been infringed often in ignorance, mark out the statesman from the mere politician, and indeed the socialist of one type from that of another type. To those who have eyes to see it this intolerance, this ungovernable fury on the part of men not great enough to govern (who think they have been flouted), marks the beginning of the eve of freedom and the onset of tyranny.

If ever there was a time when we as a profession needed the B M A or some comparable association to protect our interests, that time is surely now. But can we be certain that the B M A is even scrutinizing some of the regulations now trickling out of the Government mill, and which we may expect soon to see in ever-increasing crescendo? What kind of right has anyone, for instance, to tell us that we must attend as "temporary residents" foreign visitors who may well be luxuriating in fashionable and expensive hotels? Many of us it is true, may long have lost the boisterousness and hardihood of our student

days and only wish to live in peace with all men, but if one may utter a *caveat* it is that we may not be driven too far. To all appearances everything has now been settled amicably and all that remains to be done is to goad on the doctors and make them work. A little abuse here, a little vilification there, an abundance of misrepresentation of all kinds, and all one has to contend with is the suppressed fury of many thousands of highly intelligent beings. How will it end?—I am, etc.,

Hove Sussex

G L DAVIES

### Remuneration

SIR—When the Spens Report on the remuneration of specialists and other whole-time hospital medical officers was published the principle was expounded that clinical work should be remunerated more fairly than in the past, when high salaries meant administrative posts. The Ministry of Pensions has reviewed the salaries of hospital medical officers and has just notified them individually of the new salaries. In accordance with usual practice the notification does not indicate whether any increments will be allowed in future years, nor has any provision been made for superannuation, for this is not necessary, as the Ministry stays out of the NHS and is not bound to accept the principles of the Spens Report, etc.

The writer has been employed for some years at the maximum scale of £550 per annum (plus £100 living out allowance and £90 consolidation allowance, making £740 total remuneration), having reached this by annual increments (which had to be requested) from the starting salary of £350 per annum. On applications made in recent years I have been informed that the Ministry did not "usually pay more." The new salary has been consolidated to include all these at £890 per annum.

This information may enable hospital medical officers not employed by the Ministry of Pensions to obtain some idea of their proposed new salaries, especially as there have been rumours that the Treasury could not accept the Spens Report—I am, etc.,

"TEMPORARY" MEDICAL OFFICER

\*\* The Secretary of the B M A states. The Association will do its utmost to ensure that medical remuneration outside the NHS is brought into relation with the NHS rates negotiated on the basis of the Spens Report.

### Antenatal Treatment

SIR—I wish to draw to the attention of those practitioners who may be serving in the NHS maternity service some points which in my opinion require further thought.

A patient may, if she cares, elect to be attended at her confinement by a specialist obstetrician in a private nursing-home and pay fees, but the general practitioner on whom she depends for antenatal supervision has to be content with 3½ guineas, and he will not even qualify for this unless the patient has applied to him for treatment, and then only when "the doctor makes the initial antenatal examination and gives supervision to the end of pregnancy, including antenatal examinations at the 36th and 38th weeks." In many such cases it is the specialist who makes the initial examination, and very often the patient decides to leave home before the 38th week to reside nearer the nursing-home, if she normally resides in the country. Therefore the patient's panel practitioner cannot qualify for antenatal payment, but he can be a cheap stop-gap to serve a patient for 15s 2d per annum under National Health Service Regulations.

I contend that a patient who is prepared to spend a considerable sum on fees for nursing-homes and specialist treatment has no moral right to avail herself of the services of a doctor paid 15s 2d per year. In other words, to have her general medical service "on the cheap" so that she may go to a nursing-home is unjust. In my opinion anyone electing to have private treatment in a nursing-home should lose the right to free treatment from her panel doctor during the antenatal and post-natal period.

There is one more very important item which deserves very careful consideration. I refer to a circular letter addressed to district nurses in this area in which I reside, and for all I know it may be more widespread. I quote the lines which I think require attention. "It is no longer a condition that the mother must have the services of both the doctor and midwife, so that

you may have application made to you by mothers who require your services as a midwife without a doctor."

In this I see a practice developing with danger lurking several places. Of course it will dispense with the necessity of paying a doctor seven guineas, and that is very important. The midwife can call in the doctor in an emergency if necessary, even though antenatal supervision by the doctor might have prevented the emergency. Again, two and a half guineas will have been saved—not so good, but better than paying out seven guineas. Why not dispense with the doctors' services altogether and send all emergencies to hospital? I may be wrong, but I have a feeling that soon mothers will be advised not to go to the doctor at all in order to save expense—I am, etc.,

Callander Perthshire

F C M McILWICK

### Mileage and Midwifery

SIR,—I have not noticed any reference to one glaring omission in the NHS which should prove as great a grievance with a section of the general public as it is to a number of medical practitioners. I refer to the fact that no mileage is payable for maternity cases in rural areas.

As I see it, mileage is compensation for time wasted in attending patients at a distance, and it has been suggested to me that no mileage fee is paid for maternity cases (though curiously enough it is if one is called in by a midwife) because when the woman is on the doctor's list he is already getting paid mileage for her.

This, Sir, is not a good answer. Women often do not have their babies at their own homes in the country. May I cite two cases which I have seen during the past week? The first is a girl who lives near me, but in the present difficulty with domestic help she proposes to produce her baby in a nursing home in Bedford and wishes me to follow her there. This is quite usual, I have been doing it repeatedly for years, but not at the fee I should charge the same patient locally. Bedford is 12 miles away. Is it economically sound or sensible that I should agree to attend a first confinement 12 miles away for four and a half guineas? There are of course many excellent obstetricians in Bedford, but I brought the girl into the world and have looked after her ever since, and she wishes to be in my hands when she is confined. Where, then, is the free choice of doctor at the one time which probably most matters?

The second case is a girl now living 200 miles away a primi gravida with a very bad heart. Because I have looked after her since she was a child she is coming to her mother's home, five miles away, so that I may attend her. Does this not deserve some mileage?

Young women often move to their mothers' homes at a much greater distance to have their babies, and there are a number of villages in my practice where the nearest doctor is over five miles away. Are doctors to refuse to attend these confinements until called by the midwife, when they do get paid mileage? I wonder if this could be brought to the notice of the Minister.—I am, etc.,

St Neots Hunts

H C CRAVEN VEITCH

### Prescribing in NHS

SIR—In reference to my letter under the above heading in the *Supplement* of Aug 14 (p 84), may I be permitted to say that I am very glad to note from the Department of Health Circular ECS 27/1948 that the point raised by me has been anticipated and met by the authorities (see *Supplement* Aug 21 p 89)?

I am, however, at a loss to understand why a special form (Form EC 10A) should be needed for prescribing stocks of drugs for one's bag. I already carry in my bag, apart from its usual contents, three books of Forms EC 10 (my name being on the medical lists of three adjacent executive councils) a book each of Forms Med 1, Med 2 (A and B), Med 3, some of my own private forms for use for my private patients, a copy of the regulations for the certification of priority foods (for some reason also marked Med 2), and a few envelopes. The desk in my consulting-room is stocked with several more forms, such as certificates for glasscs (Form OSC 1 (Scotland)), Med 5, etc., and the avalanche of forms is still gathering momentum. I suggest, Sir, that to devise and issue special forms for stock prescriptions is an unnecessary wastage of public money, effort,

and time and is nothing short of bureaucracy run amok. I do not see why the ordinary forms EC 10 could not be used for this purpose with the doctor's name at the top and the mark at the space provided at the bottom of the page—I am, etc

M LICHTENSTIN

### The Capitation Fee

SIR—Whatever the reason there seems little doubt that the Negotiating Committee has lost the confidence of the bulk of the profession. One reason, and a very strong one at that, is its failure to realize the implication of service under the scheme. That one's income was likely to drop by as much as 50% should have been known not only to the Committee but to every member and steps should have been taken before July 5 to ensure that the capitation fee was adequate, which, even at 18s, it is not.

We are all guilty in that a simple calculation of the total population (45 to 50 million persons) and the number of doctors (22 000-23 000) gives a maximum number of State patients at little more than 2 000—not 4 000—which calculated at 18s per head means a maximum gross income of £1,800. Of course some men will have 4 000, but a very large percentage will have even less than 2 000. Medical practice cannot be divided up into equal areas as the planners would have us believe.

If the Association will deal with this basic fact alone ensuring that the capitation fee is in accord with present average incomes, then it can regain the confidence of its members, but a working committee for this purpose must be set up at once so that the profession can rest assured that a full-time committee of its members (men in practice cannot give the time necessary for day to day consideration of its claims) are dealing with its affairs. Whether we like it or no we must base our organization on the TUC and fight for our very existence—I am, etc

London N.C.

W. LEES TEMPLETON

### Recovering Expenses

SIR,—Cannot something be done to protect the general practitioner from the National Health Service patient who "goes private" where operations and consultants are concerned? It is one thing to admit a patient to one's local hospital for examination and treatment by the consulting surgical and medical staff there quite another to contact and arrange consultations with a consultant of the patient's own choice since this may involve one in considerable telephone expenses, not to mention interminable waiting until the great man arrives from the other ends of the earth. When such a patient is finally admitted to a private ward, I am informed by our Regional Hospital Board that I am unable to charge any fees either for my attendance on the patient or for any anaesthetics I am called upon to give irrespective of the fact that this may have to be arranged to suit the convenience of the surgeon coming from a considerable distance and outside scheduled operation times—I am, etc

Ex. B. 11

C. R. TILLY

### The BMA Under Fire

SIR—I have read with much sympathy the letter from Dr W. A. Bourne (Aug 21 p 397). I too in company with many of my colleagues was amazed that at the innumerable meetings of the profession in my area this vital subject was left unmentioned while we had rammed down our throats the so-called principles of the profession. It was I believe not until the Annual Meeting at Cambridge that serious notice of the proposals of the Ministers' proposals for remuneration was allowed to be discussed for the first time from the platform. I may turn to your leading article (p 392) and note the effect of Dr Bourne's letter which surely calls for comment. What were the principles which were considered so sacred by the pundits at the British Medical Association? What were the principles which the British Medical Association held to be sacrosanct in the decision? They were many and varied—some sound and some not—and how did they fare?

(a) The principle of fixed annual payment or capitation fee method of remuneration—After many years of negotiation the only concession from the State was to make the basic salary optional—a truly remarkable concession for such a disaffected body of men after so

(b) The abolition of the buying and selling of practices—A forlorn hope to start with, result nil, abolition remains. Was it really necessary to waste two years on this old man's dream?

(c) Right of appeal to the courts—Progress nil, as far as I am aware, after months of argument.

As this leading article is considering principles is their first line of defence, surely there was one principle they appear to have omitted, and that was the right of the general public to have a satisfactory service, which time will show is quite impossible unless the general practitioners working it are a satisfied and contented body of men, which they certainly are not at present. This is the principle which Dr Bourne has brought forward.

The British Medical Association rightly states that through the Spens Committee the remuneration of practitioners was discussed in detail and their recommendations accepted by both sides, but will they tell us what they have done towards getting that report implemented? As far as I can see—very little. They even published in April, 1948, a little booklet, *The Doctors' Case* from which they appear to be quite satisfied with the Minister's proposals. It seems strange therefore that the *Lancet* in their issue of May 15 (pp 755 and 770), should consider it worth while taking up this question on behalf of general practitioners. Furthermore, when the report of the Spens Committee on the remuneration of specialists was published, once again was the relative disadvantage of the general practitioner pointed out? Not to my knowledge, yet *The Times* of June 5 had a leading article on the subject, followed by the *Lancet* of June 12 (pp 911 and 927). I wonder why? May I be allowed to conclude by quoting the last paragraph of a letter written by me to the *Lancet* on July 5.

"I do sincerely hope with these facts in mind our next negotiating committee will take a very early opportunity of meeting the Minister to discuss the inadequacy of his present financial proposals and call on him, as he has so often promised to do, to implement the Spens Report. Remembering always their fateful words 'unless conditions are substantially improved in both these respects and on the basis of 1939 standards of money, the social and economic status and recruitment for general practice will not in the long run be maintained'."

### Domiciliary Midwifery

SIR—Your leading article entitled 'BMA Criticized' (Aug 21, p 392) suggests that there are two opposing points of view with regard to the situation which led to the movement for the reform of the BMA organization—that Dr W. A. Bourne (p 397) thinks there has been too little negotiation and that Winchester thinks there has been too much. The trouble is that the proceedings of the Negotiating Committee are not published and it is difficult to find out what has happened. My experience in regard to one particular matter may be of interest to members and certainly influenced the Winchester Division in the preparation of its memorandum.

On May 7, I wrote to the *Journal* on the subject of the position of National Health Service patients who wish to book in advance a doctor to attend at the time of delivery whether "necessary" or unnecessary. On May 10 I received a letter from the Editor to say that my letter raised an important matter of policy and that it had been passed to the Secretary BMA from whom I should be hearing in a day or two. No letter was received.

The Winchester Division sent a resolution on the subject to the A.R.M. It appeared later on the agenda and was counted out without discussion. (It was not put on the agenda of the Cambridge meeting—surely undiscussed resolutions should automatically pass to the agenda of the next meeting?) In the middle of June I interviewed a member of the Secretariat on the same subject and early in July as I had still received no letter, saw another member of the staff. Following this second interview *The Times* gave a prominent place to a letter on the same subject and finally as a result of a further letter from me to the Secretary I at last received the information asked for—namely, that the Negotiating Subcommittee of the General Practitioners Subcommittee had considered the matter and decided to take no action.

I do not know what other important matters have been considered and approved—e.g. has the profession agreed that

patients admitted to private rooms in hospital shall pay twice for the cost of maintenance, and in addition pay an "amenity" charge?

It may well be that Dr Bourne is right and that sufficient negotiation on terms of service has not taken place, or it may be that, as in the case quoted, negotiations have taken place and the pass has been sold without our knowledge. It is certainly time that the position should be clarified, and the Winchester Division feels strongly that a thorough reorganization should take place—I am, etc.,

Winchester

### Children's Medicines

SIR,—I was interested in the letter by Surgeon-Commander St George B Delisle Gray (*Supplement* Aug 21, p 91) pleading for more palatable medicines for children. Old records in our possession establish our claim that George Dunhill was growing and selling liquorice root and making "Pontefract Cakes" as far back as 1760. In those days the cake was known as liquorice cake. A few years before the war further evidence came to light that he was paying rent for land in Pontefract on which he grew liquorice root in 1749, so it becomes fairly safe to assume that he was also making liquorice cakes nearly 200 years ago. We have it on record that his purpose in introducing his liquorice cake was to make the taking of liquorice as a medicine more palatable. In those days it would appear that folks depended upon herbs and roots as the remedies for their ailments. We understand that liquorice is still very much used in present-day medicines. It certainly is a very popular ingredient in sugar confectionery, and when George Dunhill introduced his liquorice cakes nearly 200 years ago with the same idea as your correspondent, that of making medicines more palatable, he laid the foundation of the liquorice confectionery trade, as every liquorice confection there is on the world's market to-day has developed from his original introduction—I am, etc.,

### Quarterly Payment

SIR—In your issue of March 20 (*Journal* p 567) you published our letter in which we referred to the doctor becoming a branch manager for a multiple concern and working 24-hour shifts. We believe that some doctors thought we were overstating the case, thinking that private patients would exist. Our experiences reveal otherwise, because of the heavy drain of taxation in some form or other.

With the cessation of private patients no ready money is at hand, and this position is further aggravated by the fact that the doctor gets his pay (we detest using the term) quarterly. Out of four quarters' pay income tax is met in two, the remaining two goes in rent, rates, motor expenses, maid's wages, maid's insurance stamps, and indeed our own subscription of 6s 2d weekly. Indeed it looks as if nothing is left for ready-money shopping.

The present system of paying the doctor quarterly gives the Government three months' free use of all doctors' earnings. Who else but doctors would allow such a happening?—We are, etc.,

### POINTS FROM LETTERS

#### Huge Cost of Prescribing

Dr H G HARVEY (Dorchester, Dorset) writes. Since July 5 I have already written in my surgery alone 970 prescriptions, 1 per 4 patients on my list, excluding all prescriptions on my rounds, and this in the less busy summer months. One is amazed by the extras such as douches and nozzles, eye baths, pessaries, etc., one is invited to supply. More strange and more alarming still is the undoubted fact that the patients think they get all these extras free because the Government supplies them. I am firmly convinced that the huge cost of prescribing now piling up will in the short run return to the public for payment by increased taxation or other methods no less distasteful. The working classes will pay the largest share, as they represent the greater proportion of the population, and doctors may quite probably be compelled to pry by reduction of capitation rate as well as taxation.

## Association Notices

### Diary of Central Meetings

16 Thurs Publishing Subcommittee, 11 a.m.

### ELECTION BY MEMBERS OF (1) BERKS, BUCKS AND OXFORD, BIRMINGHAM AND STAFFORDSHIRE BRANCHES, AND (2) METROPOLITAN COUNTIES BRANCH

The following are the results of the election of members of Council to fill the vacancies in Groups F and I

GROUP F (Berks, Bucks and Oxford, Birmingham and Staffordshire Branches)

S F Logan Dahne (Reading)	432 (elected)
R H D Lavery (Coventry)	332
No of voting papers issued	3,210
No returned	769
Spoiled papers	5

GROUP I (Metropolitan Counties Branch)

R W Cockshut (Hendon)	416
R Hale-White (Marylebone)	908 (elected)
J A Moody (Stratford)	202
No of voting papers issued	7,151
No returned	1,538
Spoiled papers	12

### SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award

1 The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice, it includes a money award of the value of 50 guineas.

2 Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3 The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4 Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, WC1, not later than Dec 31, 1948. The prize will be awarded at the Annual General Meeting of the Association to be held in 1949.

5 No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6 If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7 Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

8 The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

9 Inquiries relative to the prize should be addressed to the Secretary.

LONDON SATURDAY SEPTEMBER 18 1948

## LOWERED INCIDENCE OF SENSITIZATION THROUGH USE OF SULPHONAMIDE COMBINATIONS\*

A NEW CONCEPT

BY

DAVID LEHR, MD

Assistant Professor Department of Medicine and Pharmacology New York Medical College  
Assistant Attending Physician Flower and Fifth Avenue Hospitals, New York City

The incidence of allergic reactions is largely dependent upon the nature of the allergenic substance and the amount and concentration of the antigen to which the individual is exposed. It is also influenced by a great number of predisposing factors such as heredity, constitution, infection, immunization, dysfunction of various organ systems, as well as meteorological and geographical conditions. It is generally recognized that within limits, the frequency of allergic reactions will increase in direct proportion with the intensity of exposure to the allergen,<sup>1,2,3</sup> particularly in types of sensitization where the role of heredity is less marked. Apparently almost every individual can be sensitized by adequate contact.<sup>4</sup>

There should be little reason to doubt that this rule applies to all drugs that can act as full antigens or haptens, including the sulphonamides. Suggestions of a definite relation between dosage of sulphonamides and sensitization have been made repeatedly almost since the inception of their clinical application,<sup>5-6</sup> and yet it is still widely believed that the incidence of allergic reactions from the sulphonamides is independent of the dosage used.<sup>8,9</sup>

A critical evaluation of the vast literature on sulphonamide therapy, greatly enriched during the recent war by exacting large scale studies of the armed Forces here and abroad gives no support to the assumed independence of dosage and incidence of sensitization. Coburn,<sup>10</sup> for instance summarizing the tremendous programme of the United States Navy on "The Control of *Streptococcus hemolyticus* with sulphadiazine, states that "sensitization did not appear to be produced by prophylaxis" even if used for as long as three to six months. His report deals with the experience gained on 600,000 men in approximately 3,000,000 man-weeks with a prophylactic dosage of 1 g. of sulphadiazine daily. The overall incidence of toxic reactions was 0.5%, as compared with 4 to 8% of human subjects who develop reactions from therapeutic dosage of sulphadiazine. "Stopping prophylaxis during alternate weeks or alternate months was followed by no increase in the incidence of reactions. Subjects who did not react to the first course of prophylaxis were not sensitive to subsequent courses. The administration of sulphadiazine therapy to a large number of men who had previously tolerated prophylaxis did not cause reactions. There was no difficulty in obtaining a satisfactory therapeutic

effect from sulphadiazine in individuals who contracted streptococcal infections while receiving prophylaxis."

Similar points of view were expressed more recently by Rosenberg and Hench<sup>11</sup> from the Rheumatism Centre of the United States Army in their evaluation of sulphonamides for the prevention of rheumatic bouts. These authors, summarizing all reports published in the previous nine years, arrive at the following conclusion: "Theoretical considerations led certain investigators to fear that some patients, treated with small amounts of sulphonamides over long periods, might become 'sensitive' to these drugs and later be unable to take them for other therapeutic purposes. However, no such sensitization was observed. Finally, there was some concern that virulent drug-fast strains of haemolytic streptococci might result from prolonged sulphonamide prophylaxis, no such eventuality has been reported."

It is the purpose of this discussion to demonstrate, with the help of data from the literature on sulphonamide therapy and our own experience with the use of sulphonamide combinations, that the incidence of allergic reactions is dependent upon the dosage of individual sulphonamides. It is further intended to show that the existence of a direct proportional relationship between dosage and production of sensitization may open a rational approach to the diminution in the incidence of drug allergy.

### Dosage of Sulphonamides and Incidence of Drug Rash and Fever

In our search of the literature for comparative percentages of sensitization with small, medium, and large dosages of sulphonamides, particular attention was given to sulphanilamide, sulphathiazole, and sulphadiazine because these three drugs have been used most extensively since their introduction into therapy twelve, nine, and eight years ago respectively, and therefore offer the richest source of comparative clinical data. One can reasonably expect that the findings for these sulphonamides will apply in like manner to other derivatives of the series.

It was realized from the start that clear-cut information could not be expected from so ambiguous and confusing a manifestation of sulphonamide toxicity. The so-called sensitization reactions actually lack any strict standards of evaluation, giving wide leeway to individual opinion and interpretation. It seemed of advantage, therefore, to limit the accounting of allergic reactions to "drug fever" and "rash," which are considered to represent the most common

\* This work has been aided by grants from the Josiah Macy Jr. Foundation, New York City, and the Schering Corporation.

indicators of sensitizations. The reservation must be made, however, that the truly allergic nature of these reactions was established by subsequent testing in exceptional instances only. Without such tests drug fever may often be confused with a flare-up of the original disease and many non-allergic skin reactions may be counted as sensitization. This fact seems to have been disregarded by many authors, who consider every rash as sulphonamide allergy and therefore an absolute indication for the interruption of therapy. Otherwise, it is contended, more dangerous signs of sensitization such as hepatitis, "chemotoxic" nephritis, or agranulocytosis may be induced. In this connexion it should be remembered that the allergic nature of these serious but fortunately rare manifestations of toxicity has not been established. In fact, especially with regard to the haematopoietic system, much evidence was presented in favour of a direct and primary tissue toxicity<sup>12</sup> or a depletion of certain essential metabolites or vitamin factors.<sup>13</sup>

A detailed discussion of the pros and cons of allergy versus primary tissue damage is beyond the scope of this paper. It should be pointed out, however, that the intentional omission of extremely rare reactions of disputed nature from this account of sulphonamide allergy will not distort the values to any extent. It should also be clear that such data as can be obtained from the literature on rash and fever undoubtedly contain an appreciable number of non-allergic reactions. Hence, in using the terms "rash" and "fever" interchangeably for sensitization or allergy throughout this discussion I am fully aware of an unavoidable inaccuracy. The figures for true sensitization are probably lower.

An attempt was made to collect data from exacting reports with large groups of patients only, however, no claim of an exhaustive survey is made. Unfortunately, many good therapeutic reports lack clarity in their figures for rash and fever. If these two reactions are listed separately, because either one may occur alone, it would seem imperative to indicate how often both reactions occurred in the same individual in order to avoid over-estimations when the total incidence of sensitization is calculated. In all such instances I chose to err on the conservative side by taking only the higher of the two figures rather than their sum and thus to present approximations of the minimum possible incidence. It will be realized in the course of the discussion that the lower figures obtained in this manner for therapeutic dosages tend to disfavour the concept for which these data were compiled. Whenever feasible, the findings of various authors were combined into larger groups. The final data obtained in this manner are summarized in the accompanying Table.

Drug	Daily Dosage in Grammes	Days of Treatment	No of Cases Treated	Incidence of Rash and Fever	References
Sulphonamide	1-2	120-240	188	1.0%	15-17
	1.5-4	7-21	1,687	0.2%	18
	6-9	5-10	1,407	>10.0%	19-20
	Routine therapy*			7.2%	14
Sulphathiazole	2-4	3-15	3,584	0%	21-26
	6	3-10	2,475	>6.4%	19, 27-33
	6-10	5-10	529	>10.0%	6, 19, 34
	Routine therapy*			11.2%	14
Sulphadiazine	1	12-90	664,840	<0.5%	35-41
	2-4	3-20	18,185	0.07%	42-45
	4-6	7-14	500	1.8%	46
	6+	2-31	2,791	2.3%	27, 30, 42, 47-52
	Routine therapy*			2.9%	14

\* These figures are based on a comprehensive compilation of the incidence of rash and fever reported in the literature.

For the purpose of correlation, the percentages of rash and fever recently published by Long<sup>14</sup> for therapeutic dosages of the three sulphonamides were included.

The table clearly illustrates a definite relation between dosage and incidence of rash and drug fever. Sulphamide given in daily amounts of 1.5-4 g for 7 to 21 days caused no sensitization in 1,687 patients, whereas 6-9 administered for only 5 to 10 days produced reactions in more than 10% of 1,407 patients. Even the worst offender, sulphathiazole, was tolerated without reaction by 3,584 individuals receiving 2-4 g daily for 3 to 15 days, whereas signs of sensitization were found in more than 10% of 529 patients when full therapeutic dosages administered for 5 to 10 days. Similarly, sulphadiazine when given in a daily dose of 1 g to 664,840 men for 12 to 90 days resulted in less than 0.5% overall toxic reaction (with sensitization obviously on a much smaller scale). Even daily dosages of 2-4 g continued for 3 to 20 days gave an incidence of only 0.07%. Approaching the routine dosage of 6 g of sulphadiazine and more, the frequency of allergic reactions rises sharply to about 2.3%. The time factor seems less significant beyond the fact that a minimum of three to five days must elapse before allergic reactions begin to appear in any significant number.

These examples may suffice for demonstration of definite correlation between the dosage of sulphonamide and the incidence of allergic reactions. It could be argued with justification, that the smallest dosages were used in most instances for prophylactic treatment of healthy individuals, or at least of persons not suffering from acute infections, thus eliminating a possible contributory factor of sensitization. However, this does not apply to the 4 g daily dosage of any of the three compounds used in the majority of instances for therapeutic purposes. In addition, it was also noted in sulphonamide prophylaxis that larger dosages result in a significant increase in allergic reactions.<sup>15-18</sup> The high incidence of sensitization observed with a 6 g daily dosage of any of the three sulphonamides could therefore not be explained solely on the basis of difference in contributory factors. It would seem that a systemic sulphonamide can be administered in a dosage of 1-2 g daily for long periods of time and even repeatedly<sup>17-36, 41, 43, 44</sup> in the same individual without the production of sensitization. The same drug in a dose of more than 4 g in 24 hours, on the other hand, induces allergic reactions in a definite and significant percentage of cases. The production of sensitization is apparently dependent upon the maintenance for some time of a certain minimum concentration of the allergen in the tissues which are to be sensitized.

This point of view is supported by many other observations. First, the so-called "non absorbable" sulphonamides like succinyl sulphathiazole (sulphasuxidine) even if given in large dosages by the oral route, will not cause drug rash and fever rather infrequently. Blood levels from these compounds are seldom higher than 1-3 mg (per 100 ml). Sulphaguanidine, on the other hand, which is far better absorbed, is known to produce an appreciable incidence of drug rash and fever.<sup>7, 9, 60</sup> In fact, Smith<sup>61</sup> who used massive dosages of this compound totalling 142 g in a 10-day period, reported 21 instances of maculopapular rash among 44 *Shigella dysenteriae* carriers. Blood levels ranged between 10 and 14 mg per 100 ml, which is unusually high for sulphaguanidine. The sensitization incidentally, was specific for sulphaguanidine, rash was not produced by sulphathiazole, sulphadiazine, or sulphamide. Further evidence for the significance of sulphonamide concentrations in the production of allergic reactions seems to lie in the fact that sensitization reactions are

local sulphonamide application can be rather frequent<sup>62</sup> and as a rule develop only at and around the immediate site of exposure (contact dermatitis), unless there was extensive systemic absorption from this local site.

There is a paucity of exact statements concerning the incidence of sensitization from topical application. Many reports on the use of sulphonamide ointments in pyogenic dermatosis<sup>63</sup> do not mention the development of sensitization. Late and Klorfajn<sup>64</sup> on the other hand, reported 26 cases of sulphonamide dermatitis among 2,289 admissions to the skin department of a military hospital, and Clarke<sup>65</sup> found 12 cases of dermatitis in 218 patients treated with sulphathiazole—an incidence of 5.5%. Walker<sup>66</sup> estimates the average incidence of contact dermatitis from sulphathiazole as 2.2% and compares it with an incidence of 5% dermatitis medicamentosa from the oral administration of this drug.

The wide variations in the incidence of contact dermatitis reported by various authors are probably due in part to differences in the type of infection treated and the duration of therapy, but are undoubtedly also influenced by the condition of the skin. In many instances the skin is largely intact; hence absorption is at a minimum and sensitization does not occur. However, the eroded areas of eczema or skin denuded of its protective outer layers by burns or wounds, will permit of deep and extensive sulphonamide penetration. The result may be a high incidence of contact dermatitis.<sup>62</sup> In fact, Lowell<sup>67</sup> recently stated that "allergic reactions were so frequent and severe in eczematous areas of the skin that the prolonged use of sulphonamides on such sites has been cautioned against repeatedly." Systemic readministration of a sulphonamide to patients sensitized locally by previous topical application will often show exclusive or predominant reaction at the locally sensitized area.<sup>60-62, 68</sup>

Finally, the dependence of sensitization on absorbability and tissue concentration of sulphonamides can also be inferred from the excellent and exacting study of Sulzberger and associates<sup>62</sup> on human volunteers. These authors investigated the incidence of dermatitis following treatment with measured amounts of different sulphonamides in the same vehicle, on standard lesions (third-degree burns) in men of the same age group, living in the same environment on the same diets at the same occupation, and under similar experimental conditions. The overall incidence of dermatitis was found to be 19% in 254 men. The distribution of sensitization for the four sulphonamides employed was 57% for sodium sulphadiazine, 22% for sulphamonomide, 7% for sulphathiazole, and 5% for sulphadiazine. Based on these remarkable results the authors conclude that "the relative incidence of sensitization corresponded to the relative water solubility of the compounds—the most soluble giving the highest incidence of sensitization." It would seem therefore that especially in systemic therapy the production of sensitization could be avoided in many instances by preventing the rise of the tissue concentration of any one sulphonamide above a certain definite level. From the data compiled in the table this level is estimated to be in the neighbourhood of 5 mg per 100 ml, allowing for some variations in the different compounds of the series. In this connection it should be pointed out that in sulphonamide preparations (e.g. of sulphamonomide or sulphadiazine daily) the dose range between 0.5 and 3 mg per 100 ml.

However, the production of sulphonamide allergy should not be confused with the response of a sensitized individual to a further dose. A further dose will elicit a vigorous and protective response. It will be that this has consequences in the interpretation that the production of

sensitization by sulphonamides may occur with small dosages as readily and is often as with full therapeutic amounts. According to Landsteiner's concept,<sup>61</sup> sulphonamides should be considered as haptens or incomplete allergens which obtain the ability to cause sensitization by combining with tissue proteins. In line with this theory, sulphathiazole and sulphamerazine, which possess the greatest protein-binding power, cause high incidences of allergic reaction, although other factors undoubtedly are of importance. (It is known, for instance, that the thiazole ring is more apt to produce sensitization than the pyrimidine ring.) The complete allergen created by combination of a sulphonamide or its metabolite with protein may be highly specific. Individuals allergic to sulphathiazole often tolerate sulphadiazine or other derivatives of the series without reaction. The specificity is also expressed by the substantial difference in the incidence of sensitization reactions established for various sulphonamides. In the majority of human beings apparently the tissue cells are able to distinguish even between closely related sulphonamides with regard to their allergenic properties.<sup>62</sup> In all such instances a combination of several sulphonamides in partial dosages should make it possible to exert full therapeutic effects and yet to "dilute" individual drug concentrations in the tissues below the level at which sensitization reactions are apt to occur. It is obvious that under these conditions the simultaneous presence of several distinct potential allergens in "non-antigenic" concentrations should be of little consequence.

If the cells of the body, on the other hand, do not distinguish between the various sulphonamides the danger of sensitization could still not be greater than if the full therapeutic dosage of a single sulphonamide had been administered. Obviously, the highest possible incidence will be determined by that drug in a combination which tends to induce allergic reactions most frequently. However, there should be no additive or even increased incidence of allergic reactions so long as individual sulphonamide concentrations are kept well below the level necessary for the production of sensitization to any one single sulphonamide in human beings with "normal" susceptibility. This concept seemed to be borne out by our experience with sulphonamide combinations.

#### Sulphonamide Combinations and the Incidence of Sensitization

Since 1944 unselected patients of all age groups suffering from acute bacterial infections have been treated with various combinations of sulphonamides at the Flower and Fifth Avenue Hospitals, as well as at the Metropolitan Hospital on Welfare Island. Adhering initially to the common belief that sulphonamide dosage is of little consequence with regard to the incidence of allergic reactions we were on the look-out for an increase in sensitization.<sup>63</sup> Instead however, we found a definite and significant decrease in the incidence of drug rash and fever, and no serious untoward reactions.<sup>63, 66</sup> Up to the present time more than 1,000 patients have received treatment with sulphonamide combinations at the hospitals associated with our institution. Although reports of allergic reactions in this series were sporadic on the whole, I have included for evaluation in the present paper only patients who were under my direct supervision or that of my immediate associates. Their number totalled 610. Of these 393 were treated with a mixture of sulphadiazine and sulphathiazole, 160 underwent therapy with a combination of sulphadiazine and sulphamerazine, and 57 were treated recently with various combinations of three sulphonamides. Equal partial amounts of the different sulphonamides were employed in all instances by the oral or subcutaneous route. Reactions

attributed to sensitization were observed in 11 cases, making it an overall incidence of slightly less than 2%. The distribution was as follows: sulphadiazine-sulphathiazole combination, 8 cases (2%), sulphadiazine-sulphamerazine combination, 2 cases (1.25%), sulphadiazine-sulphamerazine-sulphapyrazine combination, one instance of rash, apparently not allergic.

Four patients showing drug fever and/or rash were tested subsequently with small dosages of the sulphonamides to which they had been exposed. Two of these had developed allergic symptoms during therapy with the sulphathiazole-sulphadiazine combination, however, both proved to be sensitized only to sulphathiazole and not to sulphadiazine. A third patient showed no reactions while on intensive therapy with the sulphadiazine-sulphathiazole combination. Several days after discontinuation of therapy 4 g of a combination containing sulphadiazine-sulphamerazine-sulphathiazole was administered for the purpose of an absorption-excretion study. Rash, fever, and general malaise were observed within a few hours after administration, clearing completely within 36 hours.

Subsequent testing with the separate sulphonamides in the above-named order revealed, as in the first two instances, sensitization only to sulphathiazole, whereas sulphadiazine and sulphamerazine were tolerated without reaction. Finally, a patient with brucellosis treated intensively with a combination of sulphadiazine-sulphamerazine-sulphapyrazine (blood levels of 12-20 mg per 100 ml free sulphonamide), in addition to intermittent intramuscular injections of streptomycin, developed a confluent maculopapular rash over the entire body in the fourth week of treatment. Temperature at that time was continuously subfebrile. The emergence of the eruption was not accompanied by malaise or a febrile reaction. All therapy was stopped and the rash disappeared within 48 hours with residual light pigmentation. At this stage 0.5 g doses, first of the separate and then of the combined sulphonamides, were administered at 24-hour intervals. Finally, one intramuscular injection of streptomycin was given. All drugs were tolerated without reaction. Temperature fell to normal and the patient was discharged as cured.

It is obvious from these examples that two sulphonamides can be given simultaneously without the development of sensitization to both drugs. The fourth case illustrates that in many instances reactions may be counted as allergic without sufficient evidence for such a contention. Apparently the rash in this patient constituted a primary toxic response of the skin to intensive and prolonged exposure to sulphonamides or streptomycin. Dermatoses caused by hypersensitization should always be differentiated from toxic non-allergic dermatitis caused by overdosage or accumulation of a variety of agents.<sup>87</sup>

It should also be kept in mind that sensitization to several or all compounds of the sulphonamide series (group allergy) may develop in some individuals from the use of any one single representative of this group of drugs.<sup>82</sup> Obviously, if any such person develops group allergy during treatment with sulphonamide combinations it would not necessarily prove that sensitization to all components of the combination was elicited by their simultaneous administration.

The low overall incidence of rash and fever (2%) that we observed in our patients treated with sulphonamide mixtures speaks against a simple summation of such reactions by employing combinations of several sulphonamides in partial dosages. Otherwise we should have observed an incidence in the neighbourhood of 10% since more than 400 of our patients received combinations containing sulphathiazole. Actually, then, our findings indicate

a significant reduction rather than an increase in incidence of sensitization. The most plausible explanation seems to lie in the lowering of individual sulphonic concentrations in the tissues beyond the critical level necessary for the production of allergic reactions. It will be remembered that this concept was postulated earlier in this paper on the basis of the experience of many authors with single sulphonamides.

For clinical purposes a daily dosage of 2 g of any sulphonamide seems to lie safely below the amount that would produce sensitization, except in rare instances with special hypersusceptibility. Thus a combination of three therapeutically equivalent sulphonamides would allow a daily dosage of 6 g at a substantially reduced risk not only of renal damage but also of sensitization. If this concept proves correct the introduction of more than three sulphonamides into a combination should further increase the safety of sulphonamide therapy.

### Comments

The clinical use of sulphonamide mixtures, although widely accepted today on the basis of the protection afforded the kidney, is still too recent to permit any decisive statement on the question of sensitization. Our own limited experience would seem sufficient to disprove the contention of an increase in the incidence of allergy by the proper employment of combined sulphonamides. The concept of a reduced incidence, however, requires confirmation by other authors and with larger series of patients.

Of the few clinical reports on sulphonamide combinations which have been published thus far from other institutions,<sup>88-92</sup> only the one by Zeller, Hirsh, Sweet, and Dowling,<sup>92</sup> reporting on the combined use of sulphadiazine and sulphamerazine in 75 patients with meningitis, attempts to demonstrate a possible increase of allergic reactions. Unfortunately these authors arrive at conclusions which are not supported by their own results but are based on the fallacious interpretation of statistical data. Since their point of view is diametrically opposed to our concept, the evidence which Dowling and his associates present in support of their contention deserves close scrutiny.

One is struck by the unusual combined tabulation "drug fever and/or conjunctivitis, drug rash and/or conjunctivitis," which seems to attach undue significance to conjunctivitis alone as a sensitization reaction. Obviously the combined reporting of these three reactions makes it impossible to elucidate the exact position of conjunctivitis in the overall picture of reactions counted as allergic in nature. However, it seems reasonable to assume that the exceptionally high figure for sensitization reactions reported by Dowling and his co-workers for sulphadiazine (10%) which is in conspicuous contrast to all reports in the literature, is due to the inclusion of conjunctivitis as an allergic reaction.

Although conjunctivitis is seen occasionally during sulphathiazole therapy, it seems extremely rare from sulphadiazine and homologues. Plummer and Wheeler<sup>4</sup> reported one case of conjunctivitis among 1,357 patients receiving full sulphadiazine therapy without qualifying the nature of this reaction. Other authors reporting toxic reactions from sulphadiazine or sulphamerazine do not mention the occurrence of conjunctivitis. Dowling himself saw no conjunctivitis in 137 patients with pneumococcal pneumonia treated with sulphadiazine.<sup>93</sup> We have not observed any instance of allergic conjunctivitis in our large series of patients treated with sulphonamide combinations. Incidentally, no statement is contained in Dowling's report whether any attempt was made to establish the allergic nature of conjunctivitis, which is a well-known and frequent

concomitant sign of meningitis. Furthermore, Dowling *et al* increased the dosage of the combination arbitrarily by 25 to 33% above the generally accepted routine dosage of sulphonamides. Thus adult patients received 8-9 g of the sulphadiazine-sulphamerazine combination daily, as contrasted with the 6 g maintenance dose used by these authors in previous series with the separate compounds. Consequently each patient on combination therapy received an additional amount of at least 21 g of sulphonamide in the average 10 day treatment period.

While the authors neither claim nor prove the necessity of such a substantial increase in dosage when using the sulphadiazine-sulphamerazine combination, they formulate their conclusions on the advantages and disadvantages of mixture therapy as if they had used the ordinary required dosage and thus present an entirely misleading picture. Apparently based on the prevailing point of view that the incidence of sensitization is independent of dosage, Dowling and his associates attempt to demonstrate statistically significant differences between the sulphadiazine-sulphamerazine combination and the separate compounds, with complete disregard of the fact that the combination was used in a substantially higher dosage range. If we assume that the tissue cells were unable to distinguish between sulphadiazine and sulphamerazine, then an 8-9 g daily dosage of the combination which produced the highest blood levels should be expected to result in a higher incidence of allergy than either compound at a 6 g daily dosage. Even if on the other hand, sulphadiazine and sulphamerazine had acted as two distinct and specific haptens, an excessive dosage of the combination could have obviously created sensitizing tissue concentrations for both sulphonamides. The median blood levels obtained by Dowling *et al* (7.6 mg per 100 ml for sulphadiazine, 11.0 mg per 100 ml for sulphamerazine, and 14 mg per 100 ml for the combination) illustrate this possibility very clearly. In either instance an increase in the percentage of sensitization would not be surprising and would obviously not prove the point that these authors had tried to make. In this connexion it should be remembered that they did not report a statistically significant increase of sensitization with the sulphadiazine-sulphamerazine combination. In conclusion, then, the results of Dowling and his associates are explainable on the basis of the substantially higher dosage schedule of the combination and therefore carry no weight against the concept under discussion.

The recognition of a direct proportional relation between the dosage of individual sulphonamides and the incidence of allergic reactions poses many new questions which far exceed the scope of this limited discussion. To mention only a few, it should be investigated whether sulphonamides which are structurally less closely related (like sulphadiazine and sulphacetamide) are more apt to be distinguished by the cells of the body as specific allergens than isomers or homologues (sulphadiazine-sulphapyrazine and sulphamerazine). A positive finding would obviously influence the selection of sulphonamides for use in combinations. Consideration should also be given to the possible diminution of toxic manifestations other than those due to sensitization or crystalline deposition in the kidneys.

Sulphathiazine abandoned as too toxic in full therapeutic doses in the United States and sulphathiazole, under consideration for elimination, should be re-examined in the light of this concept. Both are highly potent chemotherapeutic agents with an excellent record of efficiency, especially in pyogenic, pneumococcal and staphylococcal infections. The inclusion of either drug in partial dosage combinations with sulphadiazine and sulphamerazine should lower the incidence of their untoward reactions, such as the degree. In addition the *in vivo*

antibacterial efficiency of such combinations should equal, if not surpass that of any one single sulphonamide.

Finally, the investigation should be extended to include manifestations of sensitivity elicited by many other drugs. It is known, for instance, that the principal toxic reactions from thiouracil are granulocytopenia, leucopenia, drug fever, and dermatitis.<sup>92</sup> Recently Cookson and Staines,<sup>96</sup> reviewing four years' experience with thiouracil, stated that 'most toxic effects were seen when the daily dose exceeded 0.1 g'. They found a decline in the incidence with the use of smaller doses. A similar suggestion was made by Williams and Clute.<sup>97</sup> McGavack and associates<sup>98</sup> believe that the incidence of agranulocytosis from thiouracil can be decreased by avoiding excessive dosages. Others<sup>99-101</sup> fail to find a dependence of the incidence of toxic reactions upon dosage within the therapeutic range. It seems important to point out that in these instances dosages varied as a rule within the fairly narrow range of 0.4 to 0.8 g thiouracil in 24 hours. In this connexion it is interesting to note that propyl thiouracil, which is effective in one-third the dosage of thiouracil on a weight basis, causes only 1.6% toxic reactions as compared with 9% for the latter drug.<sup>100</sup> This substantially lower toxicity of the propyl homologue, which is quite generally agreed upon,<sup>101-105</sup> has been attributed to the appreciably lower dosage schedule of this compound.<sup>106</sup> It has also been established that many patients sensitized to thiouracil can be continued on therapy with propyl thiouracil<sup>101-104</sup> or methyl thiouracil<sup>96</sup> without showing any ill effects. These observations suggest the possibility of lowering the incidence of dermatitis and fever and other toxic reactions occurring under therapy with full dosages of any one compound of the thiouracil series by using appropriate combinations of several homologues in partial dosages. Generally speaking, it should be feasible to diminish the incidence of certain untoward reactions from many drugs by employing partial amounts of therapeutically equivalent drugs of different molecular structure in combination instead of the full dosage of any one compound.

## Summary

Perusal of the extensive literature on sulphonamides reveals that in the dosage range employed in human prophylaxis and therapy the incidence of drug rash and drug fever increases in direct proportion with the dosage of absorbable sulphonamides.

At an oral dosage of not more than 2 g of sulphonamide in 24 hours none of the compounds used at present appears to produce rash or fever in any significant percentage of cases even if used for prolonged periods and repeatedly in the same individuals.

The incidence of these reactions assumes significant proportions when the dosage is increased to more than 4 g in 24 hours, and reaches even higher percentages with full therapeutic amounts of 6 g or more in 24 hours, provided medication is maintained for a minimum of three to five days.

These observations indicate that the production of so called sensitization reactions is dependent upon the repeated presence of certain critical tissue concentrations of a sulphonamide for a minimum period of several days.

In the majority of patients sensitization is specifically limited to the sulphonamide used for therapy. Hence the simultaneous administration of several sulphonamides in partial dosage should result in a reduced incidence of sensitization because it permits dilution of individual drug concentrations below the level necessary for the production of allergy.

Practical experience with combinations of two or three sulphonamides in 610 patients demonstrated a conspicuously low incidence of drug rash and fever at the full therapeutic dosage of 6 g in 24 hours.

The significance of this finding and its possible bearing upon untoward reactions from compounds of the thiouracil series, and drug allergy in general, are discussed.

The University of Sheffield has just issued in the form of attractively bound pamphlets a number of inaugural lectures delivered by newly appointed professors over the period 1945-7. Professor C H Stuart Harris lectured on "The Fight Against Infection", Professor C P Bettitt on "The Universities, Bacteriology, and National Health", Professor D H Smyth on "The Role of Physiology in Scientific Education", and Professor H A Krebs on "The Advances of Biochemistry". Copies may be obtained from the Registrar, price 1s 3d post free.

## PURPURA FULMINANS COMPLICATING SCARLET FEVER

BY

T ANDERSON, M.D., F.R.C.P. Ed

M S FERGUSON, M.D

AND

J B LANDSMAN, M.B., Ch.B.

*From the Department of Infectious Diseases the University Glasgow and Knightswood Hospital Glasgow*

A haemorrhagic form is described for each of the infectious fevers. Such illnesses are usually the most severe types, and the haemorrhages occur as a manifestation of the acute stage of the disease. Much less frequently the appearance of haemorrhages complicates an already established convalescence. The following case is illustrative of the latter form.

### Case History

A girl aged 9 complained of sore throat on Sept 15, 1947. Next day her family doctor, on the appearance of a typical rash, diagnosed scarlet fever and had her isolated in her own home. Her temperature was high and she was moderately ill for a day or two, but the course was uneventful and no specific therapy was considered necessary. In particular no serum was given and no sulphonamide was ordered then or later. During the first week of illness some oedema of the eyelids was suspected, but examination of the urine showed no abnormalities.

Progress was thus uneventful until Sept 26, when complaint was made of severe abdominal pain of sudden onset. The patient vomited. The left forearm and elbow-joint suddenly became swollen and tender. Next day haemorrhagic areas were noticed on the lobes of both ears and on the lower lip. Further haemorrhages appeared on the 28th, and by this time the clinical condition had deteriorated so severely that admission to hospital was sought.

On admission the temperature was 97° F (36.1° C), pulse 140, and respirations 24. The child was pallid and was obviously extremely ill. The tongue was furred but moist. The throat showed numerous petechial haemorrhages on the soft palate and the tonsils were enlarged, of purplish colour, and oedematous from haemorrhage. There was a small ulcer on the inner surface of the left cheek. The lower lip and the surrounding tissues were grossly swollen and were involved in a large subcutaneous haemorrhage. Ecchymoses were also present in the lobes of the ears, on the right hand, and on the buttocks. Both elbow-joints were swollen, and movement was restricted. There was surrounding ecchymotic staining. Petechial haemorrhages were also noted on the trunk. Elsewhere the skin showed a fine pin-hole desquamation, and if there had

been any doubt about the original diagnosis the typical appearance of the desquamation would have permitted a retrospective diagnosis of scarlet fever.

At this time there was little else of note in the examination except that the tip of the spleen was palpable but four hours later a considerable deterioration was noted. Fresh haemorrhages had occurred. The patient's colour was grey and she was obviously shocked. The abdomen was slightly distended and tense. The liver was now enlarged but not tender and the spleen was easily palpable. There was no tenderness in either subcostal angle. The systolic blood pressure was 90 mm, but the diastolic was unrecordable. The pulse was thin and thready.

On admission the patient had had the usual specimens (including a blood culture) withdrawn for examination and had been given 100,000 units of penicillin, since it seemed possible that the condition was a streptococcal septicaemia complicating scarlet fever. The rapid changes which occurred in the next few hours made it apparent that the correct diagnosis was a fulminant purpura. Accordingly, after further specimens were removed 5 ml of cortical suprarenal extract was given along with 500,000 units of penicillin, and these were repeated at four-hourly intervals. The question of a blood transfusion was carefully considered, but because of the risk of reaction it was decided not to give one, and, indeed, the patient's condition seemed so critical that no chance of recovery could be entertained.

The improvement 12 hours later was therefore striking and unexpected. No fresh skin haemorrhages had occurred. She was now more alert and was interested in her surroundings. Further vomiting had, however, occurred and the specimens contained altered blood. The pulse was still of poor quality, but the systolic blood pressure could be recorded more easily and varied between 95 and 100 mm. The abdomen remained tense and the liver and spleen were enlarged. Examination of the urine showed granular and hyaline casts and a large number of erythrocytes. On the evening of the 29th a few fresh skin haemorrhages were noted. By the 30th the patient was progressing satisfactorily, and although convalescence was slow the subsequent course was uneventful. The bowels were kept constipated during the first five days in hospital. At the end of this time a gentle wash-out resulted in the return of typical melaena stool. During convalescence normal results were obtained from tests undertaken to ensure that suprarenal function was satisfactory, and the patient was discharged on Nov 10. When she reported back two months later she was still somewhat anaemic but was otherwise normal. In March, 1948, she was well in all respects.

The laboratory findings are shown in the accompanying Table. From these it will be seen that the blood culture taken on admission was sterile. There can be little doubt that she had lost a considerable amount of blood on admission and that as a result there was a moderate degree of haemoconcentration. Platelets were always found, and although the figures are low

### Laboratory Findings

the important fact is the demonstration of their presence. A sternal puncture was performed, but the specimen obtained only permitted the examination of films. No significant defect was noted, there was an abundance of megakaryocytes.

### Discussion

Purpura is not a common complication of scarlet fever, indeed, it is interesting to comment that the last case recorded in Glasgow (Pratt and Frew, 1929) was also seen at Knightswood Hospital. Gibson and Hobson (1932) have described two fatal cases, both from the same family. Box (1933), who reviewed the subject of haemorrhage in acute fevers, suggested that the toxin produced a capillary lesion, which in most cases, however, was transitory. He considered that the acute glomerulonephritis of scarlet fever might be a local manifestation of this same lesion. Fox and Enzer (1938) have described four cases, two of them fatal. No enlargement of spleen or liver was noted in any of their patients, and haematological examinations were not significant of any particular disease process. Necropsy revealed no evidence of intravascular clotting, but there were microscopical extravasations of blood. In one of the patients who recovered a progressive anaemia developed.

Now, in any acute infection the occurrence of haemorrhage during the stage of the primary illness is not hard to understand, for at this time the presence of an acute infective condition with tissue destruction and generalized toxin diffusion might well induce either central changes in the blood-forming organs or damage to the endothelium of the terminal vascular channels. It is more difficult to understand why such a complication should manifest itself in a patient who has already reached a stage of convalescence. Three possibilities require consideration, the first of which can in the present case be immediately dismissed.

First, the frequent administration of sulphonamides, even to cases of mild infection, might induce some state of sensitization which would favour capillary damage. Two patients who developed purpura during convalescence from a streptococcal infection have been recorded by Rantz, Boisvert, and Spink (1945). Both had received a sulphonamide—one nine days and the other 36 days before the appearance of haemorrhage—and the authors comment that the administration of the drug confused the picture in regard to aetiology. In our patient such an explanation can be discountenanced, for it is definitely known that no medicaments were used.

The second possibility to be considered is that the condition arises from some form of sensitization induced by the original infecting agent. Any discussion of the pathogenesis of the late complications of scarlet fever, such as nephritis and non-suppurative arthritis, must take into consideration the fact that in neither is there obvious clinical evidence of an infective condition at the time when the complication arises. It would seem possible that the organism and its toxins might set up tissue reactions during the acute stage of the illness which would induce a state of hyper-reactivity, but such a hypothesis would give rise to the further suggestion that before the acute manifestations of the complication appeared some secondary stimulus to the sensitized mechanism must be applied. In recent years various workers—e.g., Gunn and Griffith (1928), Allison and Brown (1937), and De Waal (1940)—have drawn attention to the frequency with which reinfection occurs in scarlet fever wards, and such reinfection might well supply the stimulus required. In this respect it is interesting that Ehinger (1945) has shown that cases of nephritis occurred more often in individuals who had acquired during convalescence a secondary infecting type of streptococcus, and that the onset of nephritis rapidly followed the reinfection. In the present case it seems

unlikely that such an explanation can be supported, for the patient was nursed at home, in isolation, during the course of the illness. Cross-infection by a different streptococcal strain, though not impossible, is certainly improbable.

The third possibility is that after apparent recovery the original organism remains in some nidus in a state of uneasy equilibrium with the host, and that the constant slow absorption of toxic products induces gradual changes of a sensitizing nature in certain organs. Although the old theory of "septic foci" has fallen into abeyance, the experience of those who see numbers of unexplained fevers would suggest that it is certainly true that in some of these cases cure may be obtained only after the eradication of some focal sepsis which has given rise to no clinical symptoms whatever.

In the American literature the focal lesion in such cases of purpura occurring in convalescence from infection is often described as a diffuse endotheliosis (Fox and Enzer, 1938). The use of this vague term (which in no way explains the pathogenesis) infers that the condition is not primarily infective but rather is toxic in origin. Our experience with the case which we have described gives some ground for the belief that a continuing infective element may play a part in the aetiology, for the most surprising feature was the amazing degree of recovery which ensued when the body was subjected to massive penicillin therapy. We are aware that mild cases of convalescent purpura have recovered in the past, but we would emphasize that the condition of our patient on admission was grave and that death seemed imminent. Her startling improvement within 12 hours of the beginning of treatment would suggest to us that the administration of penicillin had controlled some latent infective process which was inducing the vascular damage. The presence of thrombocytes throughout, although admittedly at a low level, would argue that the haemorrhages were not due to any deformity of the clotting mechanism itself, and the state of the bone marrow, too, indicated that there was no primary damage of the haemopoietic system.

It seems to us that there is only one other diagnosis to be considered. It might be suggested that the condition was an acute fulminating meningococcal septicaemia with suprarenal apoplexy. Against such a diagnosis we can only aver that the blood culture was sterile, that tests in convalescence failed to show permanent damage to the suprarenals, and that nursed in the early stage at home in isolation, contact with a meningococcus seems unlikely. It is more probable that the cortical extract administered had merely overcome a temporary deficiency, for had the suprarenal damage been extensive one would have expected the patient to require a maintenance form of therapy.

### Summary

A case of purpura fulminans (non-thrombocytopenic) complicating the convalescence of a case of scarlet fever is described. The patient recovered. It is suggested that the possibility of a continuing or a reintroduced infection must be taken into account in a consideration of the pathogenesis of such conditions.

We wish to thank Professor D. F. Cappell, Pathology Department, Glasgow University, for his report on the sternal marrow films.

## RHABDOMYOSARCOMA OF THE URINARY BLADDER

BY

CLAUDE H. VIPOND, MD, CM, FRCSEd

*Resident Surgical Officer the Corbett Hospital  
Stourbridge Worcs*

Rhabdomyosarcoma of the urinary bladder is a rare tumour the characteristics of which have been well reviewed by Khoury and Speer (1944). These writers have found eight cases in the literature, to which they have added a further case. A tenth (the first in this country) has been reported by Minchin (1947). Here is the report of a further case.

### Case Report

A 21-months-old male child was admitted to hospital on June 1, 1947, having had retention of urine for twenty-one hours. The child had been healthy in all respects and had had no previous complaints before the onset of retention. At the time of admission there was some overflow incontinence, the bladder was apparently distended to the level of the umbilicus, and the child was in pain. A skiagram of abdomen and pelvis showed no opaque urethral calculus. After catheterization a firm mass was felt rising from the pelvic cavity to the level of the umbilicus. A tentative diagnosis of tumour of the bladder wall was made.

On June 5 a suprapubic cystotomy was performed by Mr J W Riddoch under general anaesthesia. Exploration of the bladder revealed a firm smooth tumour occupying the posterior wall of the bladder and pushing that organ forward. The internal urethral meatus could be defined, and seemed to mark the lower limit of the growth. The impression was that this growth was covered only by the mucosa of the posterior bladder wall. On attempted biopsy the haemorrhage was severe. A de Pezzer catheter was inserted and the bladder wall closed in layers. The case was now considered to be one of myosarcoma of the bladder wall.

The patient became progressively emaciated and died of cachexia on Oct 26—just under five months from the onset of symptoms. During the last few weeks of his life the suprapubic opening would no longer accommodate a catheter, and he discharged his urine through a narrow fistula.

One month before death his red cell count was 4,770,000, white cell count 13,950 and haemoglobin 71%. His erythrocytic sedimentation rate was a 63-mm fall in the first hour (Westergren technique). His blood urea at that time was 28.57 mg per 100 ml. During most of his illness the patient's temperature ranged from 99 to 99.8° F (37.2–37.7° C), but there were five or six periods of seven to ten days each in which the temperature fluctuated around 102° F (38.9° C). These probably coincided with exacerbations of his pyelonephritis.

**Necropsy (Oct 27)**—A large tumour (Fig 1) weighing about 1,788 g occupied and completely filled the pelvis extending to

FIG 2—Showing the pleomorphism of the cells ×300

the level of the umbilicus. The tumour was entirely extraperitoneal. On macroscopic examination its surface was lobulated and the cut surface varied from clear gelatinous areas to others which were yellowish white and of firm consistency. There were some necrotic areas and slight interstitial haemorrhage. The peritoneal cavity contained about 50 ml of blood-stained effusion. The visceral peritoneum was studded with small secondary nodules, especially marked in the great omentum. There were very few adhesions. The terminal part of the pelvic colon and the rectum were surrounded by growth, which appeared to have invaded their walls. The left lobe of the liver contained one large and several smaller metastases. The right lobe had several small metastases. Both kidneys were enlarged. The left showed a definite pyonephrosis and the right a hydronephrosis. The ureters were dilated and obstructed by the growth. Both ureteric orifices were found to be free from growth and there was no evidence that the walls of the ureters had been invaded. The bladder contained purulent urine. Both testes and spermatic cords were normal.

**Histological Report**—Microscopical section of the tumour showed it to be richly cellular (Fig 2). The cells were polymorphic and most of them had an oval nucleus with a prominent nucleolus and a well-marked chromatin network, the cytoplasm varied from a long rectangular type in some cells to a small perinuclear rim in others. There were also multinucleate forms containing two or three nuclei with a wide band of cytoplasm often

FIG 1—Showing lobulation and size of gross specimen

FIG 3—Showing the well-marked cross striations ×450

prolonged at one side. In all cases the cytoplasm was markedly eosinophilic and suitable staining revealed well-marked cross-striations (Fig 3) in some cells, with longitudinal striations in others. In the multinucleate forms the striations tended to be concentric. There were numerous mitotic figures.

The vascular supply was rich and tended to be sinusoidal. The supporting stroma was scanty, and there was a rich reticulum arranged around columns of cells as well as around individual cells. The histological appearance was that of a rhabdomyosarcoma. Sections of the metastases in the liver showed an identical appearance.

### Comment

This tumour was typical of its kind in that it presented itself as a cause of acute retention in an infant (of 11 cases reported 8 have occurred in infants) and that it proved fatal within 5 months (average 6½ months).

This case is unusual in that distant metastases were found. Their structure was identical with that of the tumour. Distant metastases have been described in only one preceding case—that of Mackenzie and Chase (1928).

I wish to thank Mr J W Riddoch, honorary surgeon, in whose charge this patient was treated, for encouragement to publish this case, Dr A G Marshall, pathologist to the Corbett Hospital, who performed the necropsy and supplied the histological report, and Dr W Whitelaw, Birmingham, who kindly provided the microphotographs, and who permits me to say that he agrees with the diagnosis.

## STREPTOMYCIN IN NON-TUBERCULOUS INFECTIONS

### SUMMARY OF A REPORT TO THE MEDICAL RESEARCH COUNCIL

BY

CLIFFORD WILSON, D M, M R C P

Professor of Medicine University of London Director of the Medical Unit, the London Hospital

In December, 1946, the Medical Research Council appointed a committee\* to arrange clinical trials of streptomycin in non-tuberculous infections, in parallel with the trials in certain forms of tuberculosis which have been organized by another committee of the Council. The trials in non-tuberculous infections began at five centres in London and later were extended to eleven centres throughout the country. This report summarizes the pooled results of the investigation, more detailed results will be published by individual observers. Because of the small amounts of streptomycin available, the relative rarity of suitable cases, and the wide diversity of conditions treated, experience of most infections in which streptomycin therapy may be effective is still limited. Even when, as in *Haemophilus influenzae* meningitis, a reasonably large series has been studied, the distribution of cases over so many centres has led to unavoidable variations in case selection, therapeutic procedure, and bacteriological control. For these reasons present claims must be guarded. Nevertheless, some clear-cut results have been obtained and profitable lines for further inquiry have been indicated.

These trials have been restricted to infections resistant to other forms of therapy in which bacteriological control

of treatment has been possible. With few exceptions the infecting organism has been proved streptomycin-sensitive before treatment has been begun, occasionally—e.g., in infective endocarditis—when penicillin treatment has failed, subsequent attempts to isolate the organism have been unsuccessful.

The chief value of streptomycin (apart from tuberculosis) lies in the treatment of penicillin-resistant infection due to the Gram-negative bacilli, particularly *H influenzae*, *Proteus*, *Pseudomonas pyocyanea* and *Bact coli*. The clinical disorders in which treatment has been most effective are septicaemias, meningitis, urinary-tract infection and local (superficial) infections.

### H Influenzae Meningitis

The results of preliminary trials in the United States suggested that streptomycin might be particularly valuable in this condition, a standard scheme of treatment was therefore recommended in the present investigation.

**Dosage**—*Intramuscular*, 20 mg per 1 lb (0.45 kg) body weight daily in divided (four-hourly) doses, *Intrathecal* (in saline), 50–100 mg initial dose, according to age, and 25–50 mg on subsequent days. Treatment was continued for at least seven days after cerebrospinal fluid became sterile.

**Results**—Forty-three cases were treated with streptomycin. Four of these also received sulphonamide, penicillin, or serum, in five others the CSF was reported sterile before streptomycin injections were started. Of the remaining 34 cases, the infection was controlled in 26 (76%), while treatment failed in nine. There was no significant difference in age, duration, or CSF change between the two groups, but clinically the unsuccessful cases appeared to be more severe. Where typing was carried out the organism was found to be Pittman type b. Where treatment was successful the CSF usually became sterile within 24 hours of the first intrathecal injection. Streptomycin was effective in 13 cases which had relapsed after treatment and in nine cases in which the infection had been present for two weeks or longer. Four patients relapsed after an initial response to streptomycin, but the organism remained sensitive and further treatment with streptomycin alone was successful. The principal cause of failure was the development of resistance by the organism, this occurred in seven of the nine failures, sensitivity changing from 0.5 to as high as 5,000 units in one to four days.

From this series it appears that streptomycin alone is probably as effective in *H influenzae* meningitis as any other form of treatment at present available. The development of resistance is, however, a serious drawback, and it has been decided in future trials to use a combination of streptomycin, penicillin, and sulphonamides from the start.

### Other Forms of Meningitis

Fourteen cases of meningitis due to penicillin-resistant bacteria have been treated with streptomycin. The causative organisms included *Bact coli*, *Ps pyocyanea*, *Staph pyogenes*, *Proteus*, and *Str faecalis*. In the majority of cases the meningitis developed after operation for cerebral abscess or cerebral tumour. The infection was controlled in 11 instances. Streptomycin is therefore a valuable new therapeutic agent in pyogenic meningitis due to penicillin-resistant organisms.

### Other Infections

**Septicaemias**—Five cases of subacute bacterial endocarditis due to *Str viridans* or *H influenzae* and one case of uncertain nature have been treated. With the exception

\*Professor Sir Alexander Fleming (chairman), Professor Ronald V Christie, Professor L P Garrod, Mr R Vaughan Hudson, Professor H Raistrick, Dr Robert Cruickshank, Dr F C O Valentune, Dr F R Selbie, Professor Clifford Wilson (secretary)

of the latter, the response to streptomycin has been only temporary. Two cases of septicaemia without endocarditis due to *Ps pyocyanea* or *Bact coli* have responded satisfactorily.

**Urinary-tract Infections**—A series of 61 patients with urinary-tract infection due to *Bact coli*, *Ps pyocyanea*, *Proteus*, *Staph pyogenes*, and *Str faecalis* has been investigated in 10 centres. In roughly half the cases the infection has been controlled by intramuscular administration of 3 g of streptomycin daily for one to three days. Failure has almost always been due to the development of resistance. As with other antibacterial agents, streptomycin has a limited value where there is some underlying condition which is apt to lead to recrudescence of the infection.

**Local Sepsis**—Fifty-five patients with local infections, have been treated. These include a wide variety of lesions such as infected burns, operation wounds, superficial ulcers, sinuses, abscess cavities, and septic skin conditions. The bacterial causes were similar to those detailed in the preceding paragraph. Daily applications of a saline solution of streptomycin (2 mg per ml) have been used either alone or combined with intramuscular therapy. The results are favourable, particularly in superficial lesions, provided that all necrotic tissue is removed. The employment of a standard technique is essential. Streptomycin has been used effectively as a cover for skin-grafting. In a proportion of cases failure has been attributable to the development of resistance.

**Respiratory Infections**—Chronic lung infections due to bronchiectasis and lung abscess (14 cases) have been treated by inhalation and intramuscular injection. Although a temporary reduction in bacterial content of the sputum has been noted the cases showed little if any clinical improvement. The results of a preliminary trial in whooping-cough were inconclusive. More experience is needed of acute lung infections due to penicillin-resistant organisms.

**Intestinal-Tract Infections**—Forty-two cases of infantile diarrhoea have been treated by oral administration of 2-4 g of streptomycin spread over seven days. Sensitive organisms rapidly disappear from the gut. As the infecting agent in this condition is not always the same it was to be expected that the results obtained in different centres would vary. Some centres report clinical benefit, but so far treatment has not been sufficiently controlled to warrant any definite conclusions. Further trials, in which streptomycin will be given to alternate cases, are being undertaken. A small number of cases of ulcerative colitis and of typhoid fever have been treated by oral and intramuscular administration with negative results.

### Summary

In this series of cases streptomycin has often been successful in controlling the following infections: (1) Meningitis *H influenzae*, *Bact coli*, *Ps pyocyanea*, *Proteus* and *Staph pyogenes*; (2) Septicaemia *Bact coli* and *Ps pyocyanea*; (3) Urinary tract infection *Bact coli*, *Proteus*, *Ps pyocyanea*, *Str faecalis* and *Staph pyogenes*; (4) Local sepsis *Bact coli*, *Proteus*, *Ps pyocyanea*, *Staph pyogenes* and haemolytic streptococcus.

There have, however, been examples of almost every type of infection in which the micro organisms rapidly became resistant. Courses of treatment should therefore be planned to exert the greatest possible influence from the beginning. The effect of combining streptomycin with other agents, such as the sulphonamides, is under investigation.

Owing to the short periods of administration toxic symptoms have been unusual and of slight importance. Urticarial rashes and skin irritation at the site of local application have occasionally been noted.

## "C.B.11": A NEW ANALGESIC DRUG

### PRELIMINARY COMMUNICATION

BY

W M WILSON, MB, FRCPEd

AND

R B HUNTER, MBE, MB, ChB, MRCPed  
(From the Clinical Laboratory, Royal Infirmary, Edinburgh)

In experimental studies in human beings we have recently compared the pain-relieving properties of CB 11 (4,4-diphenyl-6-morpho-linoheptan-3-one hydrochloride), pethidine, and physeptone (amidone). The method we used is a modification of that employed by Hewer and Keele (1947) in comparing the analgesic properties of physeptone, pethidine, and morphine. These authors, using a degree of ischaemic pain as their standard, found that the effects produced by 75 mg of physeptone and morphine were equivalent to those of 75 mg of pethidine. Because CB 11 has been shown in recent studies (G F Somers, personal communication, 1947) to be a more effective analgesic than morphine in rats and of low toxicity we considered it was worthy of clinical trial in man.

### Method

Ten volunteer medical students were trained to appreciate a degree of ischaemic pain produced by obstructing the blood flow to the arm by a sphygmomanometer cuff at a constant pressure of 220 mm Hg. Following occlusion the subject contracted the flexor muscles of the forearm 60 times within the space of one minute. Contractions were then stopped and the ischaemia maintained, resulting in the development of a steadily increasing pain in the forearm. The degree of pain produced in five minutes was easily recognizable, and if the ischaemia was maintained it became intolerable in 10 to 15 minutes. The subjects were trained to recognize the level of pain reached in five minutes.

An intravenous injection of one of the three drugs under trial was then given into the opposite arm. On three separate occasions 5 mg of CB 11, 5 mg of physeptone, or 50 mg of pethidine was given, the order of injection being varied in different subjects. The analgesic effect of the drugs was estimated as follows: the degree of pain at the time of injection was tabulated as 100%, an appreciable reduction of pain as 50%, and reduction to a barely perceptible level as 20%. Records of the degree of pain experienced were made every minute until the pain again increased above the original level or it was evident that the quantity of drug given had not produced any analgesic effect. The results of the experiment are given in Table I.

TABLE I

	Pethidine 50 mg	CB 11 5 mg	Physeptone 5 mg
Pain reduction to 20%	—	8	3
Pain reduction to 50%	—	1	3
No pain reduction	10	1	4

**Discussion of Results**—In each case in which analgesia was produced the effect was apparent within two minutes and lasted as long with CB 11 as with physeptone, the average duration being three minutes. After that period there was a rapid recrudescence of pain to above the original level with both drugs.

**Side-effects**—With CB 11 the injection was followed by transient dizziness, which did not last for more than five

minutes. Dizziness was slight or absent with physeptone or pethidine. With all three drugs there was a pleasant feeling of detachment, and with pethidine euphoria was marked in the majority of cases even though no relief of pain was noted. CB 11 produced pupillary contraction in all 10 cases.

**Clinical Study**—Eighteen patients suffering from pain of different types and of different degrees of severity were given CB 11 in doses varying between 10 and 30 mg. The oral, intramuscular, and intravenous routes were all employed at different times. The results are summarized in Table II.

TABLE II

	No of Cases	Complete Relief	Some Relief	No Relief
Coronary thrombosis	4	4	—	—
Teeth extraction	1	1	—	—
Pulmonary infarct	1	1	—	—
Pleurisy	2	2	—	—
Angina decubitus	2	—	1	1
Biliary colic	1	—	1	—
Gangrene	1	—	—	1
Sciatica	3	1	2	—
Neoplasm—secondary deposits	2	2	—	—
Miscarriage	1	1	—	—
	18	12	4	2

Given by mouth, 20 mg of the drug produced analgesia in 20 to 30 minutes when the pain was not severe, the effect lasting for three to four hours. When the pain was more severe, as in cases of coronary thrombosis, a dose of 30–50 mg was required to relieve the pain. No hypnotic effects were evident when the drug was given orally.

The intramuscular injection of CB 11 produced relief of pain in 10 to 15 minutes—an effect which lasted two to three hours. Very little cortical depressant action was evident. The dosage used was 10–20 mg. Giddiness and vomiting were noted only in ambulant patients and not in those confined to bed.

Given intravenously in doses of 10–20 mg, analgesia was produced within two minutes and was accompanied by a feeling of dizziness, which passed off in a short time. The analgesic effect lasted for one to two hours.

### Conclusion

This preliminary study suggests that CB 11 is a potent analgesic, comparing favourably with physeptone, and is apparently more active than pethidine under the conditions of the experiment. In a short clinical trial it proved to be effective in the relief of some types of pain.

There is no evidence at present that CB 11 is a drug of addiction.

We consider it is worthy of more extensive trial.

This study was suggested by Professor D. M. Dunlop, to whom we are grateful for advice and criticism. We are also grateful to Dr H. M. Walker, of Glaxo Laboratories, for reports of the animal experiments and for supplies of CB 11.

## ASPHYXIA OF THE NEWBORN TREATED BY ROCKING

BY

F. C. EVE, M.D., F.R.C.P.

AND

The Late N. C. FORSYTH, M.D.

The unexpected death of Dr Forsyth in November, 1947, lays on me the duty of publishing his work, which he was about to do. At Malton (Yorks) he had a large practice in midwifery of about 90 cases a year. Since 1932, when I published my rocking method of artificial respiration, he applied it to all his cases of "white asphyxia"—11 cases without a death. Hence his experience is unique and notable.

In 1947 I reported the case of a drowned boy of 14 treated (manually) by rocking (Eve, 1947). He was beyond recovery, but the colour change in his cheeks from blue to pink showed that an oxygenated artificial circulation had been created and maintained. I was excited to hear from Dr Forsyth that the same colour change had occurred in all his 11 cases *before* the first gasp. I interpreted this to mean that rocking had restored a circulation to the respiratory nerve cells, which *then* were revived enough to make the respiratory muscles gasp. The lungs, unexpanded at first, may supply only a modicum of oxygen, but apparently that is enough for the modest demands of the nerve cells provided their blood is renewed by a *circulation*, stagnation is quickly fatal, and is aggravated by accumulated CO<sub>2</sub>. Those with "white asphyxia" suffer from the enfeebled circulation of shock. Hitherto our conscious goal has been pulmonary ventilation. The first lesson learnt from these 11 cases is that we must concentrate on providing an oxygenated circulation (indicated by a pink face) to the nerve cells. If these are still viable they will then produce respiration in the natural manner. *Restore the circulation and the respiration restores itself.* The infant's heart can survive much longer, and rocking forces blood through the heart muscle.

Schmidt *et al.* (1945) were experimenting on the "gaseous metabolism of monkeys' brains". Finally the animals were killed by letting them bleed through the catheters which had been tied in the jugular veins. When heart and respiration had ceased they found (by chance) that by sucking out more blood from the jugular veins by a syringe "respiratory activity could be restarted and maintained for some time. This was confirmed by subsequent similar experiments provided the monkey was in good condition". Hence they suggest that prompt manual artificial respiration may revive electric-shock patients by creating movement of blood in the cerebral vessels.

This recent evidence strengthens my plea that in asphyxiated babies natural respiration may be started by rocking if the cerebral blood (stagnant in quiescence) can be moved onwards. The valves in the heart ensure that the movement will be towards the heart. It is rarely remembered that every millilitre of venous blood which can be coaxed from the rigid cranial cavity is inevitably (I think) replaced by a millilitre of arterial blood from the lungs.

The second new and important lesson learnt from these 11 successful cases is that rocking is certainly not harmful in shock, and appears to be beneficial. The treatment present orthodox in these asphyxia cases is concentrated shock, and consists mainly of quiescence and hope. Rocking is harmless in shock; it seems to me far preferable to this stagnation treatment.

The delegates to the first World Health Assembly will have "five weeks of very hard work," according to Dr Brock Chisholm, Executive Secretary of the Interim Commission, who points out that "for the newly formed W.H.O., the member nations, and the secretariat there will be a year of hard work in 1949 to implement the decisions of the Assembly. As for the peoples of the world there is just beginning a realization of the W.H.O. constitution, which stands 'for the enjoyment of the highest available standard of health for every human being without distinction of race, religion, political belief, economical or social condition'."

Many of the dogs used in the rocking experiments of Hemingway and Neil (1944) had their upper spinal cord cut and had the low blood pressure of "spinal shock." Yet rocking maintained their circulation and was more effective than Schafer's method or respiration by pump as regards oxygen consumption in the body. Schafer's compression method could not be expected to expand the solid lungs of the newborn infant—they need expansion before they can be compressed.

Eight of Dr Forsyth's cases were due to strangulation of the cord round the neck (nerve cells starved and anoxic), five were instrumental deliveries. He did not rock the few cases of cerebral haemorrhage which were born dead or died after a few gasps. Two recent cases were (1) A breech case, born in white asphyxia with a faintly beating heart. The face turned pink after four or five double rocks, but the first respirations occurred only after rocking for eight minutes. (2) In a boy delivered by caesarean section the heart was impalpable. The first breath occurred after rocking for seven minutes, but the change in colour from white to pink was noted some minutes *before* the first gasp. This illuminating precedence (circulation *before* respiration) was observed by Dr Forsyth in all his 11 cases. Has anyone observed it without rocking? I cannot get an answer. No one need be deterred from rocking by fear that it may increase a cerebral haemorrhage—the harm has already been done and the infant will soon be dead or better dead.

Dr Forsyth's method in his first case was to rock the baby in his large hands before the fire (success after 35 minutes). Later he found it better to stand holding the baby, wrapped in a towel and lying on its side, to his chest. Thus he could hear the respirations, and the nurse could suck mucus from the throat with a No. 10 rubber catheter. He could rock the baby—as women do—by swaying his body through some 40 to 70 degrees each way without fatigue. I have verified these angles and find them easily attained if the knees are bent a little alternately. Gravity would have longer columns of blood to act on if the infant's legs were extended and the arms raised straight overhead. Ten double rocks a minute are enough. Presumably steep angles are best.

For clarity, I have so far deferred the CO factor. In an important paper by Comroe and Dripps (1946) two adults with severe cerebral injury were investigated carefully. They survived about five hours without breathing or consciousness. Shock had reduced their blood pressure to 40–70 mm Hg. Hence their condition resembled cases of newborn asphyxia, the colour was not recorded. They were kept alive by infusions and intratracheal oxygen for two to three hours, which oxygenated their blood (fully at first) and gave them a pink colour. Yet their arterial blood was found by analysis to be poisoned by CO<sub>2</sub> (tension 314 mm Hg, equivalent to 44% alveolar CO<sub>2</sub>), which did not betray itself to the clinician. This great excess of CO<sub>2</sub> would narcotize the nerve cells, depressing respiration and blood pressure. It could be washed out only by expansion and contraction of the lungs. Schafer's method was tried, but it yielded only the "completely inadequate" tidal air of 72 to 117 c cm, owing to lack of tonus in elastic recoil. Thus "the method fails when it is most needed—in deep asphyxia which abolishes tonus. On the other hand, Eve's rocking method gave the adequate tidal air of 286 to 500 c cm, as it is independent of tonus. Circulatory benefits could not be measured."

From this paper we learn that our cases of newborn asphyxia are presumably being poisoned by excess of CO<sub>2</sub> until the lungs work. (This could be verified by blood analysis promptly after death in cerebral haemorrhage cases.) Also we do not know whether rocking expands the

lungs effectively. (This could be ascertained by x-ray examination or at necropsy in cases of failure.) Meanwhile it seems reasonable to spend a few seconds in gentle mouth-to-mouth inflation of the lungs. Then we could confidently expect rocking to oxygenate the lungs and blood, sweep out excess of CO<sub>2</sub>, and provide a circulation for the brain and heart muscle. Oxygen can be added, often with advantage. But to add 7% CO<sub>2</sub> to a probable 44% excess is deplorable poisoning.

I believe a co-ordinated research on some such lines would save many future citizens and much maternal anguish. I have tried in vain to compare Dr Forsyth's results with those obtained in hospitals by other methods. There seems a deplorable lack of co-ordinate study in these awkward emergency cases. In the U.S.A., where 30,000 babies die annually of asphyxia, Dr P. F. Flagg, chairman of the Asphyxia Committee of the American Medical Association, makes the same lament.

Some of my conclusions must be tentative until Dr Forsyth's evidence is properly confirmed—notably, that if rocking restores the circulation the respiration restores itself.

My thanks for help are due to Professor A. Hemingway, Professor Alan Moncrieff, and Dr Doreen Daley.

## GYNATRESIA: REPORT OF THREE UNCOMMON CLINICAL TYPES

BY

R. G. MALIPHANT, MD, FRCS, FRCOG

Gynaecologist, Cardiff Royal Infirmary  
(From the Department of Obstetrics and Gynaecology  
Welsh National School of Medicine)

Anomalies due to aplasia of the female genital tract are not infrequent and, depending on the extent and location of the aplasia, all varieties and degrees of gynatresia may result. The more complex congenital abnormalities are usually associated with a non-functioning uterus and are rarely of much practical importance. I have recently had under my care three unusual types of gynatresia, with certain features in common. Failure of canalization was limited in extent and localized to the cervical or vaginal segments of the Mullerian tract, and the symptomatology was dependent upon the presence of a functioning uterus. Two were examples of haematometra due to atresia at the level of the cervix, and the third was a case of hydrocolpos, a condition in which an accumulation of watery or mucoid fluid in the vagina may produce serious mechanical effects during infancy and childhood.

### Congenital Atresia of the Cervix with Haematometra

**Case Report.**—A married woman, aged 31, attended the Cardiff Royal Infirmary in September, 1945, complaining of right-sided abdominal pain. The pain had come on in attacks at irregular intervals for the previous twelve months, and these were increasing in severity. She had never menstruated. On speculum examination the portio and external os had a normal appearance, but the cervical canal was represented by a shallow blind depression, and the uterus was enlarged to the size of a three months pregnancy. At laparotomy the uterus was found uniformly enlarged and there was some distension of the

Fallopian tubes with blood. A longitudinal incision in the anterior uterine wall released about 4 oz (114 ml) of old menstrual blood, and the uterine cavity was found to end below in a blind pouch at the level of the isthmus. After separation of the bladder the anterior surface of the cervix was exposed and the vagina opened. A column of tissue, 2 cm in length, which intervened between the external os and the uterine cavity was excised and a new canal fashioned over an indwelling catheter. Three weeks later the cervical canal was easily dilatable to No. 8 Hegar, and two years after the operation the patient was menstruating regularly, she was free from pain, and the uterus was normal in size.

Haematometra is most commonly caused by occlusion of the lower end of the vagina, and it then occurs as a secondary though important complication of haematocolpos. Stagnation of blood in the uterine cavity, due to obstruction at the cervical level, is usually an acquired condition and develops as a result of scarring following operation or childbirth. Haematometra due to strictures of obstetric origin generally occurs after difficult confinements associated with infection and much cicatrization (Padovani and Vuillieme, 1931, Bernstein and Walter, 1939, Tait, 1945, Allen, 1947). Post-operative haematometra have usually been recorded after plastic operations on the cervix (Bernstein and Walter, 1939), but they have also occurred following the use of radium for benign uterine haemorrhage (Herring, 1939). In many cases of acquired stricture the stenosis is incomplete and, while blood accumulates within the uterus, there is some leakage past the obstruction. As a rule the distension by blood involves the entire uterine cavity, but Lifvendal (1933) has described a post-operative stricture of the cervix in which the haematometra was confined to the cervical canal. Retention of the menses is a quite unusual complication of carcinoma of the cervix, as this disease rarely causes stenosis of the cervical canal during menstrual life (Maliphant, 1939). Malignant occlusion of the cervix is predominantly a post-menopausal phenomenon, and pyometra is the common sequel. Most of the recorded cases of haematometra due to acquired stenosis of the cervix have required treatment by hysterectomy.

*Congenital* occlusion of the cervix is a condition of great rarity, and few examples have been recorded in the literature. Cervical aplasia is usually associated with more complex developmental anomalies of the genital tract, and the uterus is then rarely developed enough to perform the function of menstruation (Bonney and McIndoe, 1944). Bernstein and Walter (1939) described 10 cases of haematometra of congenital origin, but they were all secondary to haematocolpos. Similarly, in Simon's (1928) series from the Mayo Clinic there was not a case of haematometra due to cervical atresia in an otherwise normal genital tract, but two recorded examples of this condition have been noted in the literature. Napoleao (1931) described congenital atresia of the cervix in a woman aged 37 who had complained of attacks of abdominal pain since the age of 15. There was a hypogastric swelling equal in size to a five-months pregnancy. The vagina was normal, the cervix nulliparous, and the cervical canal was obstructed by a septum at the level of the isthmus. When this was snipped

half a litre of dark menstrual blood escaped. Monjardino (1936) also reports a case—in a young woman of 18—in which there was an imperforate septum across the cervix, and supravaginal hysterectomy was performed.

### Haematometra in Atresic Horn of Uterus Bicornis Unicollis

*Case Report*—A girl, aged 13, was brought to the Cardiff Royal Infirmary in September, 1947, on account of severe dysmenorrhoea. Her menses had started nine months previously and were regular, lasting 7 days every 28 days. The menstrual pain was mainly localized to the left iliac fossa, but also extended to the buttock and to the left leg. For the past month she had also complained of dysuria and pain on defaecation. The girl was well developed and in good condition. On examining the abdomen a circumscribed spherical swelling was evident rising from the left side of the pelvis. Rectal examination showed that this was the upper pole of a mass which filled the left half of the pelvic cavity. The cervix was normal, and the uterus could not be distinguished apart from

Diagrammatic reconstruction of haematoma of blind horn of uterus bicornis unicollis

the main swelling. The provisional diagnosis was endometrioma.

On opening the abdomen free blood was found in the peritoneal cavity, and the pelvic organs had the appearance shown in the Diagrams. From the attachments of the round ligaments it was evident that the "tumour" was the distended left horn of a bicornuate uterus. It was about the size of a large orange. The right horn and corresponding appendages were normal, and were pressed against the right wall of the pelvis. Blood from the distended horn had been forced into the Fallopian tube to form a haematosalpinx, and blood had leaked into the peritoneal cavity. The left ovary was enlarged by oedema. On incising the distended uterine horn about 1/2 pint (284 ml) of dark menstrual blood was released. No communication could be made out between this horn and the cervical canal, so it was excised together with the haematosalpinx. Convalescence was smooth, and menstruation has since been normal and painless. Histological examination of the blind horn showed typical uterine structure. Its endometrium showed hyperplasia with secretory changes.

Uterus bicornis is often symptomless and may be found accidentally in the course of an abdominal operation for some other condition. When one horn is atresic and fails to communicate with the cervical canal it may be the site of an ectopic pregnancy, but it is unusual for its endometrium to undergo menstrual changes. When this happens it is responsible for many diagnostic problems. Menstruation occurs normally from one half of the uterus, with the coincident development of a haematometra on the opposite side, and the condition is characterized by dysmenorrhoea of increasing severity. The dilated horn has usually been mistaken for a neoplasm, and the true state of affairs has become apparent only at operation. Even then, unless the relation of the round ligament to the swelling is noted, it may be mistaken for a blood cyst of the broad ligament. Wilson's (1925) case was that of a girl aged 14 who menstruated four times and complained of severe dysmenorrhoea. As the nature of the condition was in doubt, uterus and adnexae were removed. Barris (1924) has described the condition in a woman aged 20 with a history of dysmenorrhoea for 18 months. Bernstein and Walter (1939) case was that of a 27-year-old nulligravida, in whom the pre-operative diagnosis was fibroid uterus with ovar-

cyst Simon (1928) reported unilateral haematometra in an incomplete uterus didelphys in a girl aged 17 who had complained of severe dysmenorrhoea for four years. These three cases were treated conservatively by resection of the atresic horn.

This form of uterus bicornis asymmetricus, although encountered infrequently, is a condition of some clinical importance. The stagnation of blood in the blind horn produces a characteristic clinical picture, and although the findings on palpation are often indefinite the history of intense dysmenorrhoeic pain so soon after puberty should make possible the correct diagnosis and appropriate conservative treatment.

### Hydrocolpos

**Case Report**—A girl, aged 14, was admitted to the Cardiff Royal Infirmary in March, 1944, with acute retention of urine. There was a suprapubic swelling, which partly disappeared on catheterization. The vagina was occluded by a retrohymeneal membrane, and it was evident on rectal examination that it was distended with fluid. The case was regarded as one of cryptomenorrhoea with haematocolpos, but on excising the membrane, which was unusually thick, about 1½ pints (850 ml) of turbid watery fluid were released. The uterus and appendages were normal. The fluid contained many epithelial cells, and its protein content was 0.6%. It did not contain any fat globules, and was sterile on culture. Normal menstrual periods began five months after the operation and have continued normally since.

Congenital occlusion of the lower end of the vagina is not an uncommon condition, but it is rarely responsible for symptoms before puberty. The object of this report is to draw attention to a clinical entity characterized by the retention in the vagina of enough watery or mucinous fluid to produce symptoms in infancy and childhood. In the literature the condition has been described as "hydrocolpos" or "mucocolpos," and the fluid as "turbid serous," "milky," or "mucinous" in character. The retained fluid, which is regarded as the accumulated secretions of the cervical and uterine glands, contains desquamated epithelial cells with some leucocytes, and is sterile on culture. A variable amount of mucoid vaginal discharge is not uncommon in the newborn, and it is probable that in most cases of vaginal atresia there is some accumulation of uterine secretions, but not in sufficient quantity to produce symptoms until augmented at puberty by the products of menstruation. The large accumulations of sanguineous fluid in some cases of cryptomenorrhoea after one or two attacks of abdominal cramps may represent cases of pre-existent hydrocolpos into which the first few menstrual bleedings have flowed. When abnormal activity of the uterine glands coexists with vaginal occlusion such a collection of fluid may form in the genital tract that serious effects may be produced long before the onset of menstruation.

The cause of the abnormally copious secretion of fluid is obscure, but it is probably related to the activity of the uterine glands, and this is controlled by the oestrogenic hormone. The foetus *in utero* is exposed to the influence of maternal oestrogens, and also, according to Dobszay (1938), for the first two weeks after birth. The oestrogens of maternal origin are responsible for the vaginal discharge often observed in newborn infants, and also for the transient uterine bleeding and breast enlargement which may occur. During this phase there is histological evidence of increased activity of the uterine and cervical glands, and the vaginal epithelium resembles the adult type. The vaginal epithelium of adults and of infants during the first few weeks of life contains glycogen, but this is not found in the vaginal epithelium of older children before the age of puberty (Dobszay, 1938). When the infant is about 2 weeks old this change occurs in the character of the vaginal epithelium, and the uterine glands become less active in appearance (Mahoney and Chamberlain, 1940).

The morbid histology of hydrocolpos in infancy has been described in operation and necropsy specimens by Mahoney and Chamberlain (1940). They found distinct evidence of activity of the uterine glands and varying degrees of keratinization of the vaginal epithelium. The great variation in the amount of uterine secretion is considered by them to be dependent upon the degree of oestrogen stimulation, and if this view is correct increased glandular activity would be expected to occur during foetal and early neonatal life, and again shortly before puberty. It is noteworthy that most of the recorded cases of hydrocolpos fall into one or other of these two age groups. The first category includes infants who either are born with enormous collections of secretion in the vagina or have accumulated such secretions during the first few weeks of life. The second category is comprised of cases in which symptoms of fluid distension of the vagina develop shortly before puberty, when there is awakening activity of the uterine glands.

The mechanical effects of distension of the vagina are well recognized. The vagina is capable of enormous distension even in infancy, and will accommodate a large collection of fluid before the uterus is affected. In this phase the uterus is merely displaced upwards and rides on the greatly distended vagina as a small nodule. When the intravaginal fluid pressure is sufficiently increased haematometra or hydrometra follows, with reflux into the Fallopian tubes. The distension of the vagina also causes upward displacement of the bladder and stretching of the urethra and bladder neck, so the commonest initial symptom in both haematocolpos and hydrocolpos is retention of urine. Other pressure effects in infancy, such as intestinal obstruction and oedema of the lower extremities, have been described (Morris, 1945).

The mechanical effects of distension of the vagina are well recognized. The vagina is capable of enormous distension even in infancy, and will accommodate a large collection of fluid before the uterus is affected. In this phase the uterus is merely displaced upwards and rides on the greatly distended vagina as a small nodule. When the intravaginal fluid pressure is sufficiently increased haematometra or hydrometra follows, with reflux into the Fallopian tubes. The distension of the vagina also causes upward displacement of the bladder and stretching of the urethra and bladder neck, so the commonest initial symptom in both haematocolpos and hydrocolpos is retention of urine. Other pressure effects in infancy, such as intestinal obstruction and oedema of the lower extremities, have been described (Morris, 1945).

### Hydrocolpos in Infancy

It is during the first two months of life that hydrocolpos has its most serious consequences. The literature of the

Summary of the salient features of the recorded cases of hydrocolpos and hydrometrocolpos

Age	Clinical Features	
In infancy		
1 day	Found at necropsy in a baby with imperforate anus and intestinal obstruction. 1 oz (28 ml) of light yellowish mucoid material in vagina.	Mahoney and Chamberlain (1940)
2 days	Large abdominal tumour. Several ounces of turbid fluid released per vaginam.	
17	Progressive abdominal enlargement with retention of urine. Several ounces of mucinous grey fluid released <i>p.v.</i>	Rosenblatt and Woolley (1943)
3 weeks	Large abdominal tumour with retention of urine. Large amount of turbid mucoid fluid released during panhysterectomy.	Mahoney and Chamberlain (1940)
7	Retention of urine, intestinal obstruction and oedema of legs. Laparotomy followed by incision of hymen.	Morris (1945)
8	Retention of urine, abdominal swelling and diarrhoea. Laparotomy followed by incision of hymen and release of 2 oz (56 ml) of milky fluid.	Mahoney and Chamberlain (1940)
8½	Retention of urine, abdominal tumour, vomiting and diarrhoea. Laparotomy followed by incision of hymen and release of 2 oz. of milky fluid.	Kereszturi (1940)
11	Cystic swelling at vulva. 1 dr of mucus released <i>p.v.</i>	Spencer (1916)
Pre-pubertal group		
12 years	Abdominal swelling. Two quarts (2.27 litres) of milky chyle like fluid released per vaginam. Menstruated 5 months later.	Bowen (1941)
14	Abdominal swelling and backache. Laparotomy and 2,200 ml of serous fluid removed by puncture of pelvic cyst.	Althoff (1941)
14	Abdominal swelling with retention of urine. 1½ pints (850 ml) of turbid watery fluid released per vaginam. Menstruated 5 months later.	Maliphant (1948)

condition was reviewed in 1940 by Mahoney and Chamberlain, and cases have since been reported by Kereszturi (1940), Rosenblatt and Woolley (1943), and Morris (1945). It is one of the causes of large cystic abdominal swellings in female infants, and the rational and only treatment required is excision of the occluding membrane. However, without inspection of the vulva and rectal examination the true pathology is apt to be overlooked, and laparotomy with its attendant dangers in a young infant may inadvertently be employed.

The infant is distressed, and progressive abdominal enlargement and retention of urine are usually conspicuous symptoms. The main abdominal swelling is distended bladder, and after catheterization a much smaller second swelling is noted in the lower abdomen. The vagina is occluded by a bluish membrane which bulges when the child strains, and rectal examination reveals fluctuant distension of the vagina. Mahoney and Chamberlain have drawn attention to the diagnostic value of injecting radio-opaque substances through the point of atresia, and Rosenblatt and Woolley confirm the value of roentgenoscopy in establishing a correct diagnosis.

Hydrocolpos may cause alarming symptoms two days after birth (Mahoney and Chamberlain, 1940), and cases have been recorded in infants of 17 days (Rosenblatt and Woolley, 1943), 7 weeks (Morris, 1945), and 8½ weeks (Kereszturi, 1940). Morris's case of hydrometrocolpos was complicated by hydronephrosis, intestinal obstruction, and oedema of the lower half of the body. An instructive case was reported by Kereszturi in an infant of 8½ weeks. The imperforate condition of the hymen was noted, but was not considered to be of clinical significance. A barium enema showed the colon to be displaced upwards, and intravenous urograms revealed bilateral hydronephrosis with obstruction of the ureters at the uretero-vesical junction. As the infant was losing ground and the diagnosis was "pelvic tumour of unknown origin" laparotomy was performed. A cystic tumour was found filling the pelvis and pushing the bladder upwards and forwards, pressure on this tumour caused bulging of the hymen. Before the abdomen was closed 2 oz (56 ml) of milky fluid was released from the vagina by incising the hymen, whereupon the pelvic tumour collapsed. In this case the hydrocolpos and hydronephrosis were complicated by pyelonephritis with severe constitutional symptoms, and the urograms did not return to normal for a period of 15 months.

Spencer (1916) has described mucocolpos in a baby girl, 11 weeks old, in which the condition was recognized before the onset of obstructive symptoms. The mother had noticed a swelling in the vulva which became a little more prominent when the baby cried. An elliptical piece of the imperforate hymen was excised and about 1 dr (3.5 ml) of mucus escaped. Spencer stressed the importance of examining as a routine the vulvae of female babies at birth. Unless this is done any vaginal occlusion usually escapes notice until menstruation occurs, and the genital tract may then receive irretrievable damage.

### Hydrocolpos in Girls shortly before Puberty

Records of two cases of this type were found in the literature and I have now added a third. The clinical features are indistinguishable from those of haematocolpos, although the absence of monthly twinges of abdominal pain may be significant.

Bowen's (1941) case was that of a girl aged 12 who complained of lower abdominal discomfort and had a soft symmetrical mass extending from the symphysis to the umbilicus. Incision of the vaginal septum released 4 pints (2.27 litres) of milky chyle-like fluid. The girl menstruated

five months later. In Althoff's (1941) case, quoted by Morris, a 14-year-old girl complained of abdominal pain and backache for six weeks. The hymen was imperforate, and when it was punctured 50 ml of cloudy serous fluid was withdrawn. As the nature of the condition was still in doubt the abdomen was opened and 2,200 ml of the same type of fluid was obtained by aspiration of a large cyst-like structure which arose from the pelvis.

### Summary

Three types of gynatresia are described. They each had distinctive clinical features and were amenable to conservative treatment. Developmental anomalies of this order, though rare, are of much practical interest, for unless recognized they may be submitted to needlessly radical operative procedure.

## Medical Memoranda

### Acute Purpura with Neurological Complications Associated with "Sedormid" Therapy

The following case report seems to be interesting enough to merit publication.

#### CASE HISTORY

The patient, a woman aged 30, had been admitted to the Bristol Royal Infirmary three months previously for a thyroidectomy, and after her discharge had been given "sedormid" by her doctor. She had taken about 14 tablets at very irregular intervals in the course of two months. Three days before admission she had noticed a purpuric rash on her arms and legs, and on the day of admission she had had haematemesis, haematuria, and melaena.

On examination a widespread purpuric rash was seen, but the spleen was not palpable and there was no enlargement of the peripheral lymph glands. Macroscopic haematuria was present. A blood count showed red cells, 3,000,000, haemoglobin, 56%, white cells, 3,600, with normal differential count. Bleeding time was 26½ minutes, clotting time, 8½ minutes, clot retraction was very poor. Only one platelet was seen in the whole film and no estimate of their number could be made.

The next day, after a transfusion of 2 pints (1.14 litres) of fresh blood, there appeared a right-sided facial palsy of lower motor neuron type. On the following day dissociated anaesthesia (loss of pain and temperature, normal to cotton-wool) developed on the right side of the face, greater in the first and second division of the trigeminal nerve than in the third. No other abnormal physical signs were elicited, except for the right facial palsy previously noted, but the patient complained of a severe occipital headache and neck stiffness. Three days later she had had no further haemorrhages and her bleeding time was now 8½ minutes, although the platelets were still too few to make an accurate count. Her progress afterwards was uneventful, and on discharge 10 days later the platelets had risen to normal, and her bleeding time was now 4 minutes.

Nine days later she was readmitted, having had a further haematemesis and massive purpura, no platelets were seen in her blood. During the next 13 days she received 11 pints (6.25 litres) of blood—5 pints (2.84 litres) being fresh blood—and at the end of this time the platelets had risen to 3,000 per c mm and the haemoglobin

was 90%. Her condition appeared to be satisfactory for three days, but purpura developed once again and she suddenly went into coma the same night and died.

A post-mortem examination was performed by Dr R G Sandry. There were numerous petechial haemorrhages in the skin. Many small haemorrhages were also seen beneath the parietal and visceral peritoneum and pleurae, and beneath the epicardium. The spleen was enlarged to about twice its normal size and the pulp was somewhat softened. Histologically it showed no noteworthy change. The lymph nodes were slightly enlarged and purple in colour. Histologically it was evident that all the glands examined had been draining areas of haemorrhage. The bone marrow of the sternum was abundant and red, containing one area of haemorrhage. There was extension of red marrow down the shaft of the femur. Histologically, specimens of marrow taken from the sternum and from the mid-shaft of the femur were virtually indistinguishable. In both there was some hyperplasia of the erythroid series of cells. Megakaryocytes, although present, were relatively few in all sections examined. The left cerebral hemisphere was the seat of a massive haemorrhage, this being the ultimate cause of death. No haemorrhage, recent or old, could be found in the region of the descending nucleus of the fifth cranial nerve.

#### DISCUSSION

The first case of purpura due to sedormid (allylisopropylacetylurea) was published by Denig (1933), since then a number of cases have been reported in the literature. An interesting feature of my case was the accidental discovery of a positive Hess test in the patient's sister whilst using her as a fresh blood donor: no abnormality in her bleeding time or platelets was discovered, but it is suggested that there was some familial capillary abnormality in this case, and that sedormid therapy finally produced a further change in platelet production. A fatal relapse of purpura occurring nine days after discharge from hospital without further sedormid therapy is unusual, but it is suggested that the marrow, as evidenced by paucity of megakaryocytes, had been affected by the therapy.

Various therapeutic measures were tried including blood transfusion, 5 ml of intramuscular liver, vitamins C, P, and K, and 120 mg of rutin daily. Rutin, an extract of buckwheat, is stated to have an effect on capillary permeability, but in this case it appeared to have little effect.

I wish to thank Dr Orr Ewing for permission to publish this case report and Dr Sandry, of the Pathological Department, University of Bristol, for the post-mortem findings.

### Instantaneous Traumatic Forequarter Amputation of the Right Arm

A search of the literature does not show any reference to traumatic forequarter amputation of the arm. Berman (1945) discusses operative interscapulothoracic disarticulation of the arm. It is considered, therefore, that this case may be worth placing on record.

#### CASE REPORT

The patient, a healthy miner aged 23, was freeing a coal-conveyor belt which had become clogged with coal at the roller end and had stopped. His right arm was through a hole in the protective grille. The moment the belt was free it began to move rapidly, and the patient's arm was caught between roller and belt and twisted round so that it was avulsed from the body.

On admission to the casualty department he was found to be shocked but not in a serious condition. After the wound had been rapidly inspected for a serious haemorrhage anti shock therapy was begun including 2 pints (1 14 litres) of blood and 2 pints of plasma. Two and a half hours later he was operated upon under thiopentone and gas and oxygen.

On examination the skin around the shoulder showed an aperture 6 in (15 cm) vertically by 3 in (7.5 cm) horizontally, with loose and undermined edges for varying distances anteriorly and posteriorly along the chest wall. There was also a flap of skin on the anterior edge which came from the upper arm. Deeper inspection showed that there was no scapula present, and that the lateral half of the clavicle was missing. There had been, in fact a formal surgical forequarter amputation. It was difficult to insert the hand into the bed of the scapula.

The pectoral muscles had been torn through near their insertion, the serratus anterior could not be found except for a few slips on

the ribs, the latissimus dorsi was quite intact, and only portions of the levator scapulae, rhomboids, and trapezius were found. The avulsed limb was unharmed. The axillary artery had been avulsed about 1½ in (3.75 cm) from the first rib, apparently there had been no serious haemorrhage at the time of the accident owing to the avulsion nature of the injury. The brachial plexus had been severed at about the same level as the vessels.

The axillary artery and vein were ligated at the outer border of the first rib. The brachial plexus was cut short and injected with 2% procaine. Haemostasis was then secured at other points. Complete closure was possible, utilizing the flap of skin on the anterior margin of the wound. A drain was passed up into the "axilla" and a coaptation suture was inserted to hold the sutured flaps to the chest wall. Throughout the whole operation the patient's condition remained excellent. Antitetanus and anti gas-gangrene sera were given and a prophylactic course of penicillin was started.

Complete primary union was secured. The patient was in hospital for 14 days, during which time deep breathing exercises were encouraged. He complained of pain in his "phantom" limb for some time, and when this continued it was considered that the cause might be calcification in the region of the brachial plexus. A radiograph, however, showed complete absence of calcification. The nature of his "phantom" limb was peculiar, he complained that he could feel his hand and forearm but that they were attached to a very short upper arm. It may be noted that it was his hand and forearm which were primarily trapped in the machine.

I wish to thank Mr L E Sutcliffe surgeon in charge of the accident service, for permission to publish, Dr H E Pooler for the administration of the anaesthetic, and the sisters and nurses of the casualty department and accident ward for their help and aftercare of the patient.

### A Case of Poisoning by Ethylene Trichloride

A boy aged 16 had been employed at a factory for two years where one of the principal jobs consisted in the degreasing of metals by means of ethylene trichloride. Notices to the effect that this substance was dangerous were posted throughout the factory, and the boy had been particularly warned of its danger.

The degreasing of large metal parts was accomplished in a large vat containing ethylene trichloride, but it was possible to draw off the liquid into a bucket by means of a tap at the bottom of the vat, and, indeed, small metal parts were generally cleaned by rinsing them in a bucket containing ethylene trichloride. The vat was accessible to anyone working in the factory. On one occasion a workmate had found the boy smelling the liquid with evident pleasure.

At about 4 o'clock one afternoon the boy was heard to say that he was shortly going home to tea, but an hour and forty minutes later he was found in a lavatory some 30 yards (27 metres) from the vat lying on the floor with his head over a bucket the bottom of which was covered to a depth of 2 in (5 cm) by ethylene trichloride. He was dead.

At necropsy he was found to be adequately nourished and healthy. Superficial burns, reminiscent of anaesthetic burns, were seen on the left side of the face. The sweet smell of ethylene trichloride was most pronounced in the brain, lungs, and stomach, and the chief pathological changes were seen in the respiratory tract, where there was acute inflammation of all the air passages and an intense haemorrhagic oedema of the lungs. A little regurgitated vomit was found in the trachea. The cause of death was given as acute pulmonary oedema following the inhalation of ethylene trichloride, and the circumstances left no doubt that the boy had been inhaling the fumes of ethylene trichloride because he liked either the smell or the sensation which they produced.

Addition to ethylene trichloride is mentioned in the M.R.C. Report (No. 80) on the toxicity of industrial organic solvents.

The principal use of ethylene trichloride is as a degreasing agent for which purpose it is used in the dry-cleaning industry as well as in the treatment of metals. As a solvent of tar and pitch it is sometimes found in certain paints, and it has a limited use as an insecticide.

## Reviews

### MALARIA

*Pathological Processes in Malaria and Blackwater Fever* By Brian Macgrath, M.A., D.Phil. B.Sc., M.B. (Pp. 430 illustrated 35s.) Oxford Blackwell Scientific Publications 1948

The relation between the clinical signs and symptoms of malaria and the pathological changes of the disease has long excited interest and investigation. More than 400 years ago Albert Durer, it may be recalled, illustrated a letter to his physician by drawing a sketch of himself indicating his enlarged spleen and announcing, "That's where the pain is." The gross pathological lesions associated with malaria have long been recognized, but it is only during the last twenty years that improvements in technique have permitted an investigation of the biochemical lesions in malaria and a correlation of these lesions with the metabolic needs of the malarial parasites, information has thus been collected in a somewhat haphazard way. This book is the first attempt at a synthesis of the ascertained facts and as such it is an important achievement, not only because it sets out what is already known but perhaps even more because it reveals the very considerable lacunae still existing in our knowledge of malaria.

In the first chapter the author outlines the main clinical features of malaria, his account is designed more especially for those who may not be entirely familiar with the various forms of the disease in man. There follows a complete description of the morphology of malarial parasites by Dr R. H. Black, who brings to the task the knowledge that he has acquired from studies of plasmodia in cultures. He also fully discusses the physiology of the parasites, as well as the morphological changes and metabolic derangements caused by various antimalarial drugs. This is a subject which requires much further investigation. Dr Macgrath then considers the effects of malaria on the various organs of the body. Through some process which is not yet fully understood the red cells which are not actively invaded by parasites are nevertheless destroyed in considerable numbers at the time of the paroxysm. In infections due to *Plasmodium falciparum* the loss of red cells may be as high as 500,000 cells per c.mm. The author emphasizes the role of anaemia in the genesis of the lesions in the various organs, more especially in the liver and kidneys, in the genesis of derangements in the central nervous system the process of anaemia may be modified in some degree by hypoglycaemia. He concludes with a general summary of the pathological processes in malaria, such factors being considered as the still uncertain mechanism of the paroxysm, the role of haemozoin, and the tissue response to infection.

The author might have said more about the part played by humoral immunity as opposed to the phagocytic mechanism, the antithesis between latent infection and what is termed "a general humoral immunity" is not entirely clear. A few minor criticisms can be readily met in a second edition. The nomenclature of antimalarial drugs has not been satisfactorily worked out. The use of names which are official neither in Great Britain nor in America is to be deplored, as is the failure to spell consistently the names used. In the marshalling of so many references it is hardly surprising that there are occasional errors in ascribing priority, as for instance the failure to mention the pioneer work of E. K. Marshall and his colleagues (1942) on the action of *p*-aminobenzoic acid in inhibiting the antimalarial action of sulphonamides. Inclusion of an author index would improve the book.

However, it is an important and stimulating work which should be pondered over by all who are in any way associated with the problems of malaria, as there are on a conservative estimate some 700 million victims of malaria in the world quite a number of people should undoubtedly study it. Not everyone will necessarily agree with all the views put forward but some of the pundits may learn how tenuous is the evidence in favour of theories which have too long masqueraded as facts. Above all, this work emphasizes how great is the need for further investigation into the highly complex pathological processes which arise when once malarial plasmodia have entered the body.

G. M. FINDLAY

### CONSCIENCE

*The Battle of the Conscience: A Psychiatric Study of the Inner Working of the Conscience* By Edmund Bergler, M.D. (Pp. 296 \$3.75.) Washington: Washington Institute of Medicine, 1720, M Street N.W.

In the literature of psychiatry the tendency is to classify and relate mental breakdowns and to assign broad aetiological factors. While psychoanalytic writings on the other hand are confined to tracing the dynamic relations of mental development, unfolding this war of conflicting trends which give rise by repression and reaction formation to both neurosis and character, they leave the common medical reader with the impression that the person disappears in the analytic bombardment as atoms disappear into nuclear substance in the pile. It is a relief, therefore, to see in this volume actual persons not disappearing but illuminated under the fierce, cynical glare of the psychoanalytic spotlight.

While the author discusses a wide field of mental processes, he focuses his attention on the vital problem of conscience in its unconscious manifestations—the super-ego of theory which determines from an early age the deeper moral preoccupation that gives quality to character and intense suffering to the victim of mental disorder, particularly the anxiety states, the obsessions and depressions, and the torture of insomnia. He shows how much more imperative can be the dictates of this unconscious regulator of conduct and to what lengths the human being can go in meeting it by subterfuges of which he is not consciously aware. The book is amply supplied not only with case examples but with literary references and attempts at literary analysis not unfamiliar to us in psychoanalytic literature.

The author writes rarely and shows a high competence in analysis as well as a freezing penetration of human nature. This makes his approach cynical and destructive, for in his exposition he sees the working of conscience in all mental attitudes, people appear to be left with only a shred of reality sense, and the ego seems to disappear between the nether millstone of instinctive urge and the upper stone of the super-ego. If this is the *reductio ad absurdum* of analysis, then culture has certainly reduced mankind to the state of conscience-ridden eowards and hypocrites. The besetting weakness of the book, otherwise both readable and instructive, is the excessively sensational style of the chapter headings—e.g., "The Injustice Collector", "Success without Blessings of Conscience", "Neurotics who Bargain for the Electric Chair".

EMANUEL MILLER

### TEXTBOOK OF MIDWIFERY

*A Textbook of Midwifery for Students and Practitioners* By R. W. Johnstone, M.A., M.D., F.R.C.S. Ed., M.R.C.P. Ed., F.R.C.O.G., F.R.S. Ed. 13th edition (Pp. 570 307 illustrations 30s. net.) London: Adam and Charles Black 1948.

Professor Johnstone's *Textbook of Midwifery* will be familiar to many generations of medical students, for it is now 35 years since the first edition appeared. This new edition retains the well-known characteristics, and the general arrangement, including individual chapter headings, has hardly changed in the last 20 years at least. This does not imply that it has not kept abreast of the very considerable advances in the theory and practice of obstetrics in recent years, but rather that the book has always had a sound foundation. Indeed, the author is fully justified in claiming that he presents in this edition a thoroughly up to date account of what is generally accepted by the majority of modern obstetricians. The new features include a more detailed description of the maternal reactions to pregnancy, antenatal care and diet during pregnancy and lactation. The chapter on disordered uterine action has been rewritten to give a much more reasonable account of a difficult subject than is usual in textbooks. The complete segregation of hyperemesis gravidarum from the toxæmias of pregnancy is in keeping with current thought. Dr W. I. C. Morris has contributed a section on incompatible blood groups in relation to midwifery.

Apart from some inevitable differences of opinion over detail this by and large is a most satisfying textbook. On reading it again after an interval of many years it is easy to understand why it has enjoyed such continued popularity with undergraduates and practitioners. In the first place the author has

succeeded in keeping pace with advancing knowledge, and in including some useful reference to almost every condition likely to be encountered in professional examinations or in practice without increasing the size of the book to any great extent. Above all, however the book is concise and methodical, easy to read and to understand and contains views likely to meet with general acceptance rather than highly individualistic opinions. Some of the illustrations perhaps lag behind the high standard set by most modern books but this again may appeal to the student, for it helps to keep the cost within reasonable limits.

T N A JEFFCOATE

### USES OF STREPTOMYCIN

*La Streptomycine et ses Applications Therapeutiques (principalement dans la Tuberculose)* By Prof C Levaditi (Pp 218, 76 figures 350 francs) Paris Presses Documentaires 28 rue Saint-Dominique, VIIe 1948

The author of this book the director of the Institut Alfred Fournier France assembles the knowledge of the laboratory aspects of streptomycin in a form useful for research workers and others. His aim also is to review the clinical applications of the antibiotic, particularly in tuberculosis but in this he has been less successful partly because of the rapidly changing picture given by clinical trials. Professor Levaditi and his colleagues have themselves been active in experimental work on streptomycin, and many of their results are given; they tend to confirm previous conclusions rather than to break new ground. The book can be recommended for its concise presentation.

P D ARCY HART

### HOSPITAL ADMINISTRATION

*Problems of Hospital Administration* A Report on a study based upon interviews with 100 Hospital Administrators located in various sections of the United States Charles E Prall Director Joint Commission on Education (Pp 104 No price given) Chicago Physicians Record Company

The profession of hospital administrator is a more distinct one in the USA than in Britain, and training courses have been established by many bodies including universities. Those responsible for devising courses and curricula have realized that, until it is clearly understood what the functions of a hospital administrator are or ought to be, provision of adequate training to an approved standard is impossible.

A joint Commission of Education was set up by the College of Hospital Administrators and the American Hospital Association to make a wide survey of the field and to submit what would be in effect a careful job-analysis of the work of a hospital administrator. This book is the result of the investigations and is based largely on interviews with 100 leading administrators chosen because of their approved experience and efficiency some being medical some lay and representative of all varieties of hospital voluntary and State, large and small. Every aspect of hospital work is touched on the questions and answers covering every conceivable problem both of policy and day-to-day running. The book is a useful record of facts and on it the Commission of Education will base its recommendations for an optimum curriculum. This book and the Commission's recommendations should be of great value to all interested in hospital control and management in Britain.

ANDREW TOPPING

Sir Alfred Pearce Gould's well known manual *Elements of Surgical Diagnosis* ninth edition revised by Sir Cecil Wakeley (Cassell 15s) has reached the age of 63 years and is still popular—a fact that speaks well for its usefulness for the law of survival of the fittest operates efficiently in the medical literary world. Sir Alfred was one of the best surgical teachers of his time and on looking into this volume one can see the secret of his success for here we find lucid exposition clear differentiation of signs and symptoms and definite direction leading to accurate conclusion. The last edition was by the original authors son but Eric Pearce Gould unfortunately died during the recent war. Sir Cecil Wakeley has ably revised the text. He constantly used the book when a student and appreciates exactly what its function is in the education of the student. The revision was therefore (as he says in the preface) a labour of love and he has preserved the excellent tradition of the book. We can cordially recommend it to the student and for that matter to the teacher of surgery.

### BOOKS RECEIVED

## SAFETY IN CHEMICAL WORKS

The aim of those responsible for safety in factories is so to control the physical environment and so to stimulate the consciousness of workers that accidents are reduced to unpredictable events. Experience shows that most accidents could have been foreseen. Appropriate rules and regulations can be drawn up for the prevention of serious accidents, but compliance with the law alone will not necessarily reduce their incidence. The human factor, so hard to define and so real in the daily life of a factory, still dominates the picture. Were it possible so to operate industrial processes that the incalculability of man had no relevance to the problem of safety, then the incidence of accidents would fall sharply. The story of the manufacture of the atom bomb illustrates what can be achieved in spite of the extreme dangers involved. The concentration of effort on safety measures and the availability of means to implement them are still far from adequate in the general body of industry. Because of expense perfect environmental conditions cannot be provided, and reliance is placed on exhortation, propaganda, and training in safety. The response to this is improving but is still far from satisfactory.

In the chemical industry the opportunities for calamitous accident are many. Injuries, explosion, poisoning, and industrial disease menace the worker continually. In spite of technical conformity with the legal requirements the conditions in many chemical factories are bad. An almost traditional belief that the industry is necessarily a dirty one inhibits the efforts which are necessary to establish better practice. The workers who are employed in the industry are, in general, of the less developed type and correspondingly difficult to educate in co-operative safety measures. At the present time almost insuperable obstacles prevent even the best of managements from improving or renewing plant and from introducing those amenities which not only improve the self-respect of the worker but also are essential if safe working is to be attained.

Even in the chemical industry most accidents are not due to chemical faults but to falls, falling objects, moving machinery, tools, handling goods and articles without machinery, stumbling over obstructions, and the like. Probably not more than some 5-10% of all accidents in chemical factories are due to actual chemical products. This figure must, of course, be distinguished from the incidence of industrial diseases such as poisonings,

dermatitis, tumours, and eye affections. It is obvious that in order to reduce accidents in chemical factories the rules of safety applicable in other types of industry must be no less earnestly applied: good housekeeping, clean working, good lighting, heating, and ventilation, effective guarding of machinery, and mechanical methods of lifting and transporting machinery and products.

The Chief Inspector of Factories in his Report<sup>1</sup> for 1945 points out that training schemes for new entrants into factories do not sufficiently emphasize safety principles. 'The general recommendation that men should be informed of the physical and chemical hazards of their work is much more difficult to carry out in chemical factories than would at first appear. Mere statement of hazards is not enough. Workers, ever pressed for more production, become confused by a multiplicity of instructions. What is wanted is clear and simple explanation by various experts (chemists, engineers, doctors), and then a demonstration on the plant of accident-prevention techniques, followed by practical lessons on the steps to be taken by the worker to protect his own safety and that of others. The worker must co-operate. If he cannot he should leave the industry or be placed where he can do no harm.'

The Works Safety Committee of the Association of British Chemical Manufacturers have recently issued a new edition of the *Safety Rules for Use in Chemical Works*, first drawn up in 1938. Presented as a series of more or less dogmatic statements, it provides a summary of all those matters which ought to be considered by works managements, and there are useful references to relevant parts of the Factories Act and the Chemical Works' and other Regulations. Stress is laid on the appointment of safety officers in works of appropriate size. These officers should advise heads of departments who bear direct responsibility for safety. A corollary to this might be that all such persons should undergo a proper course of training and an examination before being given these great responsibilities. It is true that engineers and chemists learn much about safety precautions by experience, especially in large organizations, but in the many small factories the situation may be very different. Safety committees, rightly insisted on in these *Rules*, can contribute much, provided that the most intelligent workers serve on them.

Before manufacturing or using new or unfamiliar materials it would seem reasonable to expect employers to obtain information on their toxicity. Some of the larger chemical firms have gone to considerable lengths in this, and the recent establishment of a toxicological unit by the Medical Research Council may be expected to meet the needs of many concerns unable to carry out their own tests.

The rules which are concerned with the establishment of health services in chemical works are on the lines more or less generally recognized as desirable. The appointment of first-aid men to deal with emergencies is the only possible expedient in small factories, but a part-time medical officer should be retained to train such men and to advise on medical matters. In factories employing 250 or more persons (on any period or shift) an ambulance room should be provided and a Statc-registered nurse employed

<sup>1</sup> *Annual Report of the Chief Medical Inspector of Factories for the Year 1945*  
London: H.M.S.O.

<sup>2</sup> *Model Safety Rules for Use in Chemical Works*. Part I. 3rd (revised) Edition  
1947. Published by the Association of British Chemical Manufacturers. London.

<sup>3</sup> *The Chemical Works Regulations*. Statutory Rules and Orders 1922. No. 731  
London: H.M.S.O.

First-aid men in such factories should have their functions closely defined and be trained not to exceed them

One of the biggest problems in the chemical industry is to obtain the co-operation of the workers in the practice of routine ablution. The importance of this is obvious on medical grounds, but just as important is the undoubted fact that dirty workers are a menace in a chemical factory. Where workers on dangerous processes are supplied with complete sets of working clothes (under- as well as over-clothes) it is in general found that reluctance to bathe is overcome. But it is very different with other workers even when comfortable facilities are provided. There is frequently reluctance to undress, fear of colds, and anxiety to get away from the works. The medical officer has an important function to perform here, and it is not an easy one.

The ABCM Rules advise the provision of barrier creams to protect against dirt and skin hazards. The multiplicity of such preparations on the market is sufficient indication that a really effective cream is not available. The discouragement of dirtiness and the prevention of dermatitis depend largely on good working conditions and methods, good ablution practice, and a proper sense amongst management and workers that the chemical industry need not be as dirty as tradition has made it appear.

Medical men employed whole-time in large chemical factories have unique opportunities of making important contributions to safety as well as interesting themselves in more obviously medical matters. To have the required authority it is essential that they should either possess some chemical training or acquire by study a competent knowledge of the main chemical principles underlying the processes carried out in the factory. The more understanding of chemistry the doctor possesses, the more confidently will he be able to raise his voice in the councils of the industry.

### SULPHONAMIDE COMBINATIONS AND SENSITIZATION

In a paper published in the *Journal* last year Dr David Lehr, of New York, advocated the use of mixtures of different sulphonamides in place of single drugs.<sup>1</sup> He made the important observation that when such mixtures are given each drug retains its individual solubility in urine. It is thus possible by administering two or three drugs instead of only one greatly to reduce the risk of undue precipitation and hence obstruction in the kidney or urinary tract. Such mixtures also have a lower toxicity than an equal dose of a single compound, in spite of the fact that the better absorption of small doses of each compound produces higher total blood levels. Clinical experience of the use of these mixtures had also been satisfactory: they were therapeutically effective, rarely produced crystalluria, and were singularly free from toxic effects.

Dr Lehr returns to this subject from another point of view in the opening pages of this issue. He is concerned here to inquire whether these mixtures, which he now refers

to as "combinations," are more or less likely to cause sensitization than an equal dose of a single drug. It is clearly desirable first to determine so far as possible what are the factors governing sensitization when a single drug is given. In particular, how is sensitization affected by dose and duration of treatment? It would certainly appear a formidable task and might even seem an impossible one to obtain an answer to this question from the literature. Dr Lehr has nevertheless succeeded in doing this, and presents his evidence and the authority for it in a single concise table. The only criteria of sensitization adopted are drug fever and rash, and the only drugs considered are sulphanilamide, sulphathiazole, and sulphadiazine. A point worth noting is the frequency of sensitization phenomena during the administration of sulphathiazole; it has even been proposed to abandon its use in the USA on this account.

The main conclusion, which is amply supported in connexion with all three drugs apart from one anomalous finding in the lower dosage range of sulphanilamide, is that the smaller the daily dose the less likely is sensitization to occur. This is true regardless of the duration of treatment. A small dose continued for months is unlikely to sensitize—witness the results in the prodigious number of 664,840 patients given 1 g of sulphadiazine daily for up to 90 days. These were mostly members of the US armed Forces who took part in the mass prophylaxis of respiratory tract infections attempted during the war. On the other hand, doses of 6 g or more daily of any of these three drugs given for only a few days are much more likely to cause sensitization. The difference is slightest in the case of sulphadiazine, much the least apt of the three to produce such effects at all. It appears, therefore, that up to 2 g daily of any sulphonamide can be given for long periods or repeatedly with little risk of sensitization; the danger is from heavy doses, usually given for only short periods in the treatment of severe infections. This is a conclusion of fundamental importance and calls for general recognition. Evidently high blood and tissue concentration favour the development of sensitization; Lehr suggests 5 mg per 100 ml as the level which must not be exceeded. He points out that the notorious frequency of sensitization following local application is explicable on the same lines: if the drug is applied to eczematous skin or to any wound, absorption will lead to very high concentrations in the underlying tissues. It is generally believed that sulphonamides can function only as haptens, the actual sensitizing agent being a compound of the drug and a body protein. This view is supported by the behaviour of sulphathiazole, which has both a high protein-binding power and a marked tendency to cause sensitization. It would be interesting if it could be shown *in vitro* that combination with protein is affected by sulphonamide concentration in the manner which these clinical findings would lead one to expect.

The final step in the author's argument rests on the fact that sensitization is usually specific for a particular drug. Whether one sulphonamide or two or three are administered at the same time, the possibility of sensitization will depend on the concentration of each drug attained in the blood and tissues and not on the total sulphonamide

<sup>1</sup> *British Medical Journal* 1947 2, 934

concentration when more than one is given. It is therefore to be expected that sulphonamide combinations will be less likely to sensitize than the same dose of a single drug. Lehr's personal experience bears this out. He gives particulars of 610 patients treated with combinations of two or three drugs, including sulphathiazole, in whom the frequency of sensitization nowhere exceeded 2%. Perhaps more extensive experience of the method is called for before this conclusion can be finally accepted, but an excellent case has been made out for an additional advantage of sulphonamide combinations. The same principle might be applied when several compounds of related but different molecular structure have the same pharmacological action. Thiouracil derivatives are said to behave independently in the production of sensitization and might therefore with advantage be used in combination for the same reason. If the possibilities of this principle are borne in mind, other useful applications of it may well be found.

### REMOVAL OF CHILDREN'S TONSILS

It is questionable whether any clinical problem has caused more controversy in medical and surgical circles or more confusion in the minds of lay people than that which was tersely stated by Kaiser in the title of his book, *Children's Tonsils, In or Out?* In a recent letter to this *Journal* Mr T B Layton<sup>1</sup> urged that the medical profession as a whole should reconsider its approach to tonsillectomy. The operation—perhaps more correctly described in bygone days as tonsillotomy—is an ancient therapeutic measure, for Celsus referred to it about A.D. 50, and Paulus of Aegina performed it with a hooked instrument about A.D. 670. But it is only during the past thirty years or so that the operation has been performed frequently—too frequently in the opinion of many clinicians. Dr J Alison Glover, who has recently reviewed the subject from the paediatrician's point of view, shares this opinion, and he suggests that further critical and controlled investigation of the indications for and after-results of the operation are needed.

An intelligent layman might well be surprised that doctors have not reached definite conclusions about the value of an operation which has been performed upon more than one and a half million children attending public elementary schools in England and Wales during the past twenty years, and he might argue that there should be a close season for tonsils until more is known of their functions. Though there is little precise knowledge on this point, few will deny that the location and cellular structure of the tonsils suggest that they contribute to the individual's defence against bacterial attack. They may be compared to filters, with the cervical lymphatic glands as a second line of defence. If it were possible to say from the patient's history and from direct observation that tonsils are diseased beyond natural repair there would be a good case for their removal and, if it were surgically possible, their replacement by healthy tonsillar tissue. The chief difficulty confronting the clinician is one of diagnosis. Simple hypertrophy—probably a beneficial reaction—should no longer be regarded as an indication for operation, and the history of frequent recurrences of tonsillitis is now thought to be a more valuable guide than clinical examination of the tonsils. Statistical evidence, though difficult to assess, would appear to favour a conservative attitude towards operation.

There are, however, certain aspects of tonsillectomy which justify definite statements. It is a major operation,

never urgent, and it should be preceded by a period of observation of six months after the completion of any necessary treatment of teeth and sinuses, it should not be performed in winter or early spring, nor when infectious diseases are prevalent, and it seldom improves the condition of patients with established systemic diseases such as nephritis or rheumatism.

### RAT-BITE FEVER

There are two forms of rat-bite fever caused respectively by *Spirillum minus* and by *Streptobacillus moniliformis* which some workers prefer to call *Actinomyces muris*. The disease has been reported from various parts of the world, but the spirillar type, which is the commoner, is specially prevalent in the Far East, including Japan, where it is known as "sodoku". There are clinical differences between the types, but the diagnosis can only be made bacteriologically. The usual history is that some days after being bitten by a rat or, more rarely, some other animal the victim succumbs to a severe febrile illness characterized by marked prostration, muscular pains, glandular enlargement, and a maculopapular or morbilliform rash. After an initial febrile period lasting two to four days the temperature subsides until the occurrence of the next bout of fever a few days later, fever of this relapsing type may last for weeks or months. The case fatality in the past has probably been from 2 to 10%.

Brown and Nunemaker<sup>1</sup> reviewed both types of rat bite fever and observed that while they may be clinically indistinguishable there are certain features characteristic of the streptobacillary type. The incubation period, often only two or three days, is shorter than the usual one to three weeks of the spirillar disease, the fever is less regular in its relapses, joint pains and actual arthritis are common, and there are few local inflammatory signs in contrast to the spirillar type, in which the wound becomes inflamed, the regional glands enlarged, and the dark purple rash may appear around the bite before becoming generalized.

The laboratory diagnosis of rat-bite fever is made by isolation of the infecting organism from the blood or from serum at the site of the local lesion. *Spirillum minus* may be found in dark-ground preparations of blood or peritoneal fluid from mice or guinea-pigs inoculated with infected material. *Streptobacillus moniliformis* is pathogenic to mice, but can be more quickly demonstrated by culture of the patient's blood in digest or serum broth, subcultured on Loeffler's medium. The organism grows rapidly in fluid media in the form of fluffy "cotton-ball" colonies. Microscopically it consists of chains of coccobacilli and pleomorphic filaments showing beading and swellings. It is Gram-negative in young cultures. The agglutination test<sup>2</sup> has been found useful in diagnosis by some workers if a uniform suspension of the organisms is carefully prepared. A leucocytosis is found in both types of disease, and a considerable proportion of false-positive Wassermann reactions have been reported, especially in cases due to *Spirillum minus*.

A report of a case of infection with *Streptobacillus moniliformis* by Dr I R W Lominski, Dr A Stewart Henderson, and Professor J W McNee in last week's *Journal* (p. 510) serves as a reminder that rat-bite fever may be a hazard of the laboratory worker. This case, which was of considerable severity, responded dramatically to treatment with penicillin. A dosage of 12,000,000 units was given over a period of seven days, but there is evidence that a smaller dosage would probably have been effective. The disease due to *Spirillum minus* responds both to arsenphenamine and to penicillin. The frequent occurrence of

<sup>1</sup> *British Medical Journal* 1948 2 310  
<sup>2</sup> *Arch. Dis. Childh.* 1948 23 1

*Streptobacillus moniliformis* in the nasopharynx of rats was confirmed by these authors, who found the organism in 7 out of 10 of the rats from the batch containing the original culprit. Rat bites, however, are not necessarily the only cause of human infections: two outbreaks in the United States of the disease known as Haverhill fever have been traced to the consumption of raw milk presumably contaminated with this organism.

### TRAINING OF NEUROSURGEONS

The long training that a neurosurgeon must undergo before he is a competent, let alone an experienced, practitioner, and the large number of cases that now come into his hands, compel him to devote his time exclusively to their study and treatment. The Society of British Neurological Surgeons, whose planning committee under the presidency of Sir Hugh Cairns has recently issued a report on the provision and training of neurosurgeons,<sup>1</sup> is therefore to be congratulated on emphasizing that recruits to this important specialty should have obtained the F.R.C.S. and spent another year in the practice of general surgery. As the committee points out, "The neurosurgeon must be on familiar ground when he operates on the neck, the back, and in the retroperitoneal and extrapleural spaces." He would also gain valuable experience from spending six months as a house-officer in a department of medical or surgical neurology. Training the apprentice in neurosurgery is the next stage, and the committee considers that 4½ years are required—perhaps less for a man experienced in some other branch of surgery.

The first year of this period should be spent as a senior house officer in neurosurgery, and the second in gaining experience of the physiology of the nervous system, or its anatomy, pathology, or bacteriology. Six months' training in medical neurology follows, and in the third year the apprentice acts as registrar in the department of neurosurgery. In the fourth year the registrar works also as a "domiciliary consultant." The last is a particularly interesting recommendation, for it would keep the registrar in close touch with the clinical problems of his specialty and at the same time help to relieve the shortage of neurosurgeons available for home visits. The committee forestalls criticism that a relatively junior man would be doing this work by pointing out that most consultations in neurosurgery are requested to decide whether the patient needs treatment in hospital or not. A training such as this leading to a career of arduous and sometimes excessive work, is not a rosy path as the committee frankly admits: it is perhaps strewn with rarer flowers, though, and may in future be less hazardous financially than has been the case hitherto.

Over the last 20 years the work of the neurosurgeons has increased steadily and the committee suggests that a centre of about 50 beds is necessary to serve the needs of a million people. Regional and area centres should be created in association with the universities and the teaching or large general hospitals, not in isolation; the regional centre would have two complete surgical teams and about 50 beds, the area centre about 25 beds. The neurosurgical team would have at its head a director holding the university post of reader or professor, an assistant director also on the university staff, associate neurosurgeons, a chief assistant (registrar), and house-surgeons. There would also be anaesthetists, a neuropathologist, and special facilities for radiography and electroencephalography. Auxiliaries trained in massage and occupational and speech therapy would be required, a nursing staff rather larger than that in other branches of surgery, social workers, and a secretariat.

Medical neurologists and psychiatrists must be readily available for consultation. A scheme of this magnitude might have seemed a luxury before the recent war, but there can be no doubt of its necessity now, when there are many thousands of cases of head injury alone every year—a high proportion of them sustained in road accidents.

### BIOCHEMICAL CHANGES IN HYPERTENSION

The search for humoral factors in hypertension continues unabated. The possibility that the suprarenal cortex may be involved has been considered from time to time because of the occurrence of high blood pressure in Cushing's disease. In a recent report Fisher and Hewer<sup>1</sup> draw attention to an unduly high frequency of suprarenal cortical hyperplasia in patients with high blood pressure. Perhaps allied to this is the temporarily beneficial effect of a low salt diet in reducing the blood pressure. Selye<sup>2</sup> has shown that experimental animals treated with desoxycorticosterone develop hypertension associated with an increase in the ratio of sodium to chloride in the serum. This was caused mainly by a decreased chloride value, though there was an occasional increase in sodium. In a series of 38 hypertensive patients it was found that the Na/Cl ratio in the serum was increased above the normal upper limit of 1.4 up to figures as high as 1.6 and over. In addition to this, the glyco-corticoids formed by the suprarenal cortex were present in the urine in increased quantities though the 17-ketosteroids were low. The administration of ammonium chloride in doses of 6 g daily was sometimes effective in changing the serum sodium chloride ratio towards the normal. No favourable responses, however, were obtained in hypertensive patients over the age of 50 with diastolic pressures less than 100 mm. This group probably contains those patients with arteriosclerosis affecting mainly the large vessels. Selye includes in his paper a chart showing the progress of a patient with malignant hypertension whose blood pressure fell to normal while he was being treated with ammonium chloride. This report is interesting, but there is rather too much speculation about the connexion between hypertension and rheumatism. None the less, the biochemical facts, if substantiated, should be further investigated. There is a hint here of a possible new method of treatment.

### IMPROVEMENTS IN ARTIFICIAL LIMBS

Research work on artificial limbs must be very satisfying, and at the same time embarrassing, satisfactory because if one idea fails it is possible to try again with the same patient, and embarrassing because the amputees themselves are so full of ideas. According to the Second Report<sup>3</sup> of the Standing Advisory Committee set up by the Ministry of Pensions, no fewer than 153 suggestions were received during the year, 82 of them were worth serious consideration, the rest being discarded as impracticable or referred elsewhere because they were outside the scope of the research department's activities. Yet every proposal, even though not immediately or remotely acceptable, is acknowledged and recorded, so that nothing is lost and full credit may be given to the inventor of a useful device. Particular attention has been paid to development of the suction-socket leg which enables a patient with an above-knee amputation to dispense with suspensory apparatus. Experiments carried out in Great Britain eighteen years ago were unsuccessful, but the Germans have had better fortune and the committee was favourably impressed with the appliances in use in Germany. There are two problems, the socket and the valve. The fit of the socket must be accurate, and, since

<sup>1</sup> *Notes on the Neurological Needs of the Population and the Training of the Neurosurgeon*.

<sup>2</sup> *J. Path. Bact.* 1947, 59, 605.

<sup>3</sup> *Canad. med. Ass. J.* 1947, 57, 325.

<sup>4</sup> Published by H.M.S.O. Price 4d.

the stump is liable to changes in shape, adjustment must be easily possible. In this respect the wooden socket is the best so far, and thirty are now on trial. The disadvantage of the one-way outlet valve is that a gradually increasing negative pressure develops in the socket which ultimately damages the stump. The research department has now devised a double-acting valve and has determined what are the most satisfactory positive and negative pressures. Valves can be tested and set to give the proper pressure variations, and it is now possible to replace a valve without requiring the patient to attend the limb-fitting centre.

Great ingenuity has been displayed for many years past in the design of mechanical hands, but hitherto the controlling mechanism has been too complicated and the hand itself too heavy. However, one inventor who was given the full facilities of the research workshop, though himself failing to produce a satisfactory appliance, left his designs with one of the Ministry's contractors, who has now succeeded in producing what may prove to be a useful hand. A working liaison with research departments in the United States has led to the development of another type of mechanical hand in which only the three lateral digits are mechanically controlled, this appliance is under trial. Much care has been taken with the design of ancillary appliances such as crutches, sockets for holding tools, the tools themselves—pliers, combs, etc., telephone fixtures, and rubber sleeves for double below-elbow amputees. These sleeves enable a double amputee to bath and wash entirely unaided, and in common with many other products of the research department were most favourably received when Dr Craft, the officer-in-charge, demonstrated them in the course of his visit to the United States and Canada last year. Preoccupation with the design of artificial limbs and appliances has left little time for the investigation of new materials in the construction of limbs, but in certain situations nylon webbing and cord have proved much superior to leather.

This second report, written with clarity and modesty, shows that this country is determined to maintain its pre-eminent position in the provision of appliances for those who have had the misfortune to suffer amputation. It is easy to say that more work could have been done had the establishment of the research department been larger, but perhaps it is best that its growth should be gradual—it is not yet three years old—and the strong advisory committee responsible for these investigations will no doubt press for expansion if and when they think it desirable.

### GLANDULAR FEVER AND THE NERVOUS SYSTEM

For many years it has been appreciated that glandular fever may be complicated by signs indicating infection of the nervous system. Perhaps suspicion is most frequently aroused by severe headache. In these cases it is usual, as Lumsden's<sup>1</sup> experience has shown, for the cerebrospinal fluid to be unaltered, but very rarely a neutrophil meningeal reaction may occur.<sup>2</sup> Less uncommon than this is a lymphocytic pleocytosis accompanied by meningitic, meningo-encephalitic, or encephalitic symptoms. Tidy<sup>3</sup> has found five examples recorded, and he has made the suggestion that "benign lymphocytic meningitis" is, in fact, frequently due to glandular fever. A varied assortment of cranial and peripheral nerve palsies have been noted as complicating this disease, but these nervous sequelae cannot be fitted into any clinical classification. A recent

report has added yet another complication. Ricker<sup>4</sup> and his colleagues have described two examples of the association of glandular fever with what they term the Guillain Barré syndrome. In both patients glandular fever was complicated by a rapidly ascending flaccid paralysis, with little or no sensory loss and without sphincter disturbance. Within a week of onset respiratory paralysis caused the death of both. Neither showed the albumino cytologic dissociation Guillain<sup>5</sup> has claimed as characteristic of his syndrome, and perhaps it is wiser not to apply the eponymic label. Nevertheless here is another and a serious neurological complication to be added to the heterogeneous collection already noted during the course of glandular fever.

### ROCKEFELLER BENEFACTIONS

In his report<sup>1</sup> on the work of the Rockefeller Foundation in 1947 Dr Raymond Fosdick, the president, says that representatives of the Foundation in that year visited practically every country in the world with the exception of Bulgaria and the Soviet Union. Visas for these two countries could not be obtained, nor was it possible to establish contact with their scholars and scientists. Since the end of the war the Foundation has budgeted for the expenditure of \$5,500,000 on various activities in the war crippled countries of Europe. The aim has been first to get research started again by providing equipment or support to a few universities, libraries, and research centres, and secondly, through conferences and improved circulation of specialist journals, to re-establish the contacts of those institutions with each other and with the rest of the world.

The Foundation works in five divisions—namely, natural sciences, medical sciences, humanities, social sciences, and public health—and all have taken part in the post-war effort. The largest grants were made to Britain, France, Denmark, Holland, Norway, Sweden, and Switzerland. The recipients of grants in Britain included the Burden Neurological Institute, Bristol, Edinburgh University, for research in neuro surgery, neurology, and psychiatry, the Medical Research Council, for the purchase of scientific equipment, Cambridge University, for research in cell physiology at the Molteno Institute, King's College, London, and Leeds University, for research in molecular biology, Oxford University, for research in organic chemistry in the Dyson Perrins Laboratory and on antibiotics in the Sir William Dunn School, and for studies in agricultural economics, the Royal Institute of International Affairs, towards the expense of producing a history of the war and of the peace settlement, and the British Museum, for the establishment of a micro-film library. The Foundation had to decline 2,500 applications for financial aid during 1947. These included 18 public health projects and 70 "cures, remedies, investigations of theories, and inventions."

The largest grant the Rockefeller Foundation made in 1947 was \$10,000,000 to the China Medical Board. This is one of the Foundation's oldest interests. The China Medical Board, which was created in 1914 as an operating division of the Foundation, was responsible for the erection and development of the Peking Union Medical College, one of the world's important medical training centres. The college has lately been reopened, after its deterioration in the hands of the Japanese, though it is working under far from perfect conditions. The China Medical Board is empowered to give financial support to other similar institutions in the Far East or even in the United States, but so long as opportunity remains for effective work in the College in Peking that is its first responsibility.

## MEDICINE AS A PLANNED ECONOMY THE BIOCHEMIST'S VIEW

BY

EDWARD B HENDRY, B.Sc., Ph.D., M.B., Ch.B.

(From the Biochemistry Laboratory, Royal Infirmary  
Edinburgh)

In a recent paper entitled "Where Are We Going?" Roberts (1948) has commented on the extraordinary increase in the number of patients submitted to x-ray examination, and he very aptly describes the work of an x-ray department as "accelerating towards infinity." The biochemistry department suffers in the same way and in this laboratory we have encountered a similar extraordinary increase in the number of specimens submitted for analysis. The graphs shown here are exactly comparable to those in Roberts's paper. The total number of

Total number of analyses (upper graph) and total number of blood analyses (lower graph) during the period 1928-47

analyses carried out annually reached a steady level about the year 1933, and maintained this level, averaging about 12,000 per annum, without much fluctuation until 1945. In 1945 the total number of analyses was 10,384, in 1946 it rose to 15,203, and in 1947 it rose again to 23,218.

During the last two years the process of "acceleration towards infinity" has forged ahead to such an extent that one is forced to draw the only logical conclusion—that, unless this acceleration stops, the doctors of the near future will be concerned solely with the problem of collecting specimens to the exclusion of all other forms of practical medicine. This is a far more serious threat to the art and practice of physic than any Government legislation, and to the non-clinical onlooker it is a tragedy that the teachers of to-day do so little to arrest this degeneration of modern medicine. The taking of a good history and the recording of the results of a careful clinical examination should be the main duty of every junior clinician; the collection of a large bundle of assorted laboratory reports ought to be regarded as an indication that the doctor's clinical knowledge and powers of observation are deficient in certain respects. Some laboratory examinations are so valuable that they now form an essential part of medical practice, but they are comparatively few in number. It is the duty of every clinician to find out what these methods are to use them properly and to avoid the others.

There are many factors at work in this recent development of hospital biochemistry, and it is interesting to classify the main sources of the trouble.

### Factors in the Biochemist's Burden

First, there is the natural desire for the clinician to produce as complete a case history and examination as possible. This leads to the sending of specimens to the pathologist, bacteriologist, biochemist, and haematologist departments with sundry requests,

while the patient is sent to the x-ray department with instructions to have an electrocardiogram done on the way back to the ward. This type of investigation often has its origin in the self-recrimination undergone by the doctor who has, at a less experienced stage in his career, failed to detect a lesion which might have been spotted had he carried out some simple laboratory examination. He is, quite rightly, determined not to make the same mistake twice. But he should remember that no case history can ever be complete.

Secondly, there is the type of doctor who must have as much laboratory confirmation as possible for every clinical diagnosis, irrespective of any signs or symptoms. If a patient is in the terminal phase of chronic nephritis there is little point in taking a specimen of blood for determination of urea, creatinine, cholesterol and alkaline phosphatase. Even the teaching value of such analyses is small.

Thirdly, there is the clinician with an inquiring turn of mind who would be better described simply as a "figure-collector"—a snapper-up of unconsidered analyses. All biochemists are painfully familiar with the type who approaches him at frequent intervals with a request to churn out a series of analyses of, say, the blood lactic acid in a thousand consecutive cases of pro-lapsed polycystic kidney. The number of such workers unacquainted with the *Index Medicus* is remarkable. A variant of this species is the investigator who refuses to accept the standards quoted in the literature. He is determined, at any cost, to have a series of analyses of his own, although quite prepared to use the established methods on a series of cases exactly similar to those studied by other workers.

Fourthly, there is the group who wish to practise venepuncture. They are to be commended, not condemned, for they are endeavouring to master a technique. But is it necessary to send the sample to the biochemist with a request that he determine the "BUN" (*anglice* blood urea nitrogen)?

Fifthly, there is the type of clinician who annoys the laboratory with analyses under the impression that the results are of diagnostic or prognostic importance, when in actual fact the results are of neither scientific value nor clinical significance. The biochemist certainly bears the brunt of this type of work. A barium meal on an elderly gentleman with some gastric disturbance may be negative, but the negative result is of great value to both doctor and patient. A blood urea estimation is of absolutely no value whatever in 95% of the cases in which it is done.

Lastly, there is a comparatively small group who can give no reason whatever for having sent a request for certain analyses, and when the matter is discussed with them they are quite agreeable to the specimens being discarded.

There are many other subsidiary causes of the extra burden placed on the modern laboratory. Analyses which are repeated at regular time intervals arouse no enthusiasm in the scientific mind unless the time interval corresponds to some alteration in the metabolism of the patient. And yet a clinician who repeats an analysis every twenty-four hours would be highly indignant if anyone were reckless enough to suggest that he is really trying to correlate metabolism with the movement of the solar system.

Biochemical forms which detail the amount of blood required for the commoner analyses may help to eliminate technical sources of trouble, but they are a psychological blunder, since they suggest analyses which are of no real value in the case which is being investigated. There is always the type of mentality which says "We might as well have the potassium done at the same time." This argument is valid only in the examination of the cerebrospinal fluid, where every additional lumbar puncture carries the risk of a meningeal infection, however careful the operator.

The biochemistry department suffers from another peculiar disadvantage—it expresses its results in terms of simple figures, and in the various branches of general medicine one is frequently (or shall we say always) as far away from things mathematical as it is possible to get without entering the field of pure philosophy. The attempt to correlate the patient's changing condition with a series of changing numbers is a natural one, but it is seldom very helpful.

The final result of all these factors may be summed up in one sentence the truth of which cannot be denied *If this "acceleration towards infinity" continues unchecked without a simultaneous and corresponding increase in laboratory facilities and staff then the accuracy (and hence the value) of all biochemical analyses will accelerate towards zero*

### A Pernicious Trend

The pernicious effects of the modern trend to reduce clinical work to a series of reports has its repercussions in the ward and in the operating theatre as well as in the laboratory. A pathologist who recently visited Edinburgh from a distant part of the Empire produced the startling information that the surgeons with whom he is associated will not operate on any case unless the patient's blood sugar and blood urea have first been determined. In consequence he has had to employ an all-night staff so that these estimations may be made before even an emergency operation for acute appendicitis will be carried out.

In this country it is a common procedure to determine the blood urea before certain types of operation—e.g., suprapubic drainage, prostatectomy, etc. Whether or not these results are ever taken into *serious* consideration is a point on which I am not quite clear, but it is a solemn thought that some unfortunate patient may have the question of operation partly decided by a skilled technician who is fighting an increasingly hopeless battle against time and who is surrounded by a multitude of requests for analyses 90% of which can be classified only as rubbish. A colleague recently returned from abroad, tells me that in some of the hospital laboratories which he visited the biochemistry department is divided into two sections: a small part of the work which is judged to be of importance is carefully carried out by a highly trained and experienced staff, the rest is dealt with by junior trainees. It is a pity that a scientific subject should be driven to such practices. Many would reply that the obvious procedure is to extend laboratory facilities as much as may be required to cope with the work. This is no answer. Geometrical progressions are tricky things to handle: once the indices are removed and the answer reduced to a simple number the result is astounding.

### Unfulfilled Hopes

Nor can this recent fantastic increase in the number of biochemical analyses be defended on the grounds that more reliable procedures for investigating disease have been evolved in the last few years. The reverse is the case. Thirty years ago, when biochemical investigation was getting into its stride, great hopes were entertained that here we would have a truly scientific method of investigating and assessing disease reliably. These hopes have not been fulfilled, and the disappointment is not a reflection on biochemistry. Experienced biochemists realize that very little (c. 5%) of the so-called "routine biochemistry" is of any value to anyone, and since the task of collecting specimens is a self-imposed one the clinician who raises a complaint against the increasing number of forms to be filled up receives little sympathy from the biochemist who receives more than his fair share of them.

The argument that the clinician sees the patient while the laboratory staff do not is an argument which often carries far too much weight. Consider the following typical case:

Patient	Male, aged 36	Specimen	oxalated venous blood
Diagnosis	Myocarditis	Investigation required	plasma proteins

The biochemist accepts the diagnosis as correct. So far as he is concerned, it is quite sufficient that the patient's symptoms even suggest the diagnosis which is given. If the patient has an infective condition such as myocarditis it can safely be assumed that the plasma albumin will be a little below normal, the globulins will be normal or slightly raised, and the fibrinogen will be normal. We may therefore ask three questions: Irrespective of the actual figures obtained on analysis (i.e., the extent of the deviations, if any, from the normal), will the report (a) modify or cancel the physician's diagnosis? (b) affect in any way the physician's prognosis? (c) affect the treatment of the patient in any important detail? The answer in each case is an emphatic "No!" Such examples could be multiplied several thousand times over per annum.

A wholesale condemnation of modern biochemical analyses may lead the clinician to conclude that laboratory staffs regard their departments as superfluous hospital appendages. There is a germ of truth in the conclusion. Most departments dread the day when hospital laboratories will be open to the outside consultant and to the family doctor. If these two classes of doctor send in an amount of work proportional to their numbers (and there is no valid reason why they should not), then every laboratory in the country will be reduced to complete chaos.

### The Question of Blood-urea Analysis

Much of the congestion in the biochemistry department is caused by a multiplicity of requests for determinations of the blood urea. During the past 20 years blood-urea estimations have formed about one third (22–39%) of the total number of biochemical analyses in this laboratory. Of the first thousand reports sent out at the beginning of this year no fewer than 533 contained blood-urea analyses. An examination of the diagnoses sent on the accompanying forms is of some interest.

	Total	Percentage
No diagnosis given	62	12
Prostatic hypertrophy	29	95
Other diseases of the renal tract	66	
Hypertension	74	137
Other cardiovascular diseases	63	
Other diagnoses not included above	239	45

In only two of these 533 analyses was the blood urea part of a van Slyke urea-clearance test. The 239 unclassified diagnoses were described under 64 different diseases or symptoms. The commonest were: pre-eclamptic toxæmia (21 analyses), diabetes (20), thyrotoxicosis (15), haematemesis (13), peptic ulcer (11), jaundice (8), hepatic cirrhosis (7), bronchitis (7). Other diagnoses included: iritis, sciatica, asthma, hysteria, dyspepsia, sarcoidosis, silicosis, epilepsy, leukæmia, polycythaemia vera, anaemia, spondylitis ankylopoietica, exfoliative dermatitis, scurvy, trigeminal neuralgia, and abdominal pain.

A random blood-urea analysis is probably the most useless and, at times, the most misleading of all laboratory examinations. Its great popularity appears to rest on the following points: (1) No other constituent of blood is so definitely associated in the mind with an anatomical system as the urea is with the renal tract. (2) The renal system cannot be examined adequately at the bedside. (3) A complete examination of the renal system must include certain laboratory tests—e.g., examination of the urine. (4) There is a popular impression that the blood urea is a measure of the patient's renal function. This belief was abandoned about 30 years ago by biochemists. (5) The blood urea is elevated in so many diverse pathological conditions that it is the laboratory test *par excellence* which is most likely to give an abnormal result when done at random. Of the 533 blood-urea-nitrogen analyses referred to above, 62% were over the normal upper limit of 15 mg per 100 ml.

There is little space left to consider two other important aspects of this problem. First, a laboratory inundated with routine analyses has no time to spend on the more elaborate methods used for research: the quickest methods are the best. Secondly, there is the question of expense.

### Conclusions

Everyone must agree that the alarming increase in the number of laboratory examinations must stop or be stopped before things reach the stage of becoming a farce. It would give rise to a good deal of acrimonious debate whether the process should be stopped by the clinician, by the laboratory staff, or by the hospital authorities, and whether it should be stopped by innuendo, persuasion, coercion or compulsion. I do not propose to allow myself to become entangled in this delicate point.

It is a great pity that there is not more collaboration between clinical and laboratory staffs. Active co-operation could do much to root out obsolete and unnecessary work, and in other cases investigations which are of importance could be substituted with advantage to all.

Roberts, F (1948) *British Medical Journal*, 1, 485

## RADIOACTIVE ISOTOPES FOR CLINICAL RESEARCH

The Medical Research Council has made arrangements to obtain from the United States Atomic Energy Commission limited quantities of certain radioactive isotopes for medical research including therapeutic investigations. Further, it is expected that regular supplies will soon become available from Canadian sources and later from British sources.

The Medical Research Council now invites institutions to submit for consideration detailed programmes of research in the clinical field. The application should include adequate information on the following matters:

- (a) Specification of the radioactive isotope required
- (b) Quantity desired (Radioactive isotopes with half-lives of less than 30 days may be allocated in fulfilment of one request, in amounts sufficient for six months' needs, with arrangements for shipments at intervals of not less than one week.)
- (c) Date and rate of deliveries desired
- (d) Name of institution at which the materials will be used
- (e) Names and research experience of investigators who will use the materials. This list should include the names of the radio-therapist and physicist who will collaborate in the research.
- (f) Purposes for which the materials will be used, with methods of administration and the dosage required.
- (g) Protection and safety measures to be employed to safeguard the health of the workers. (Useful guidance will be found in *Introductory Manual on the Control of Health Hazards from Radioactive Materials* which may be obtained from the Medical Research Council on application.)
- (h) Proposed financial arrangements, including the sources from which the applicant will defray the cost of the materials.

Information under these headings except (h) is required by the United States Atomic Energy Commission as a condition for the supply of the isotopes. The Commission supplies isotopes only for accepted lines of research of which the results are fully published and which are conducted in institutions open to visits from investigators in this field of all nationalities. The Medical Research Council should for this reason be notified of any such visits by workers from other countries to any institution receiving the isotopes through its agency.

Progress reports must be made to the Medical Research Council every six months. In the case of therapeutic investigations the institution supplied with radioactive isotopes must undertake to register the patients treated according to the cards and system of the Statistical Department of the General Register Office.

In its application to the Medical Research Council for radioactive isotopes the institution must give the following undertakings:

- 1 That the materials supplied will not be used in any manner other than that disclosed in the application.
- 2 That the institution will maintain all necessary protection and safety measures to avoid the special hazards to health arising out of possession, handling and use of radioactive isotopes, and will allow inspection of all such protection and safety measures by representatives of the Medical Research Council.

The Medical Research Council wishes to emphasize that the supplies of radioactive isotopes are at present limited and that the materials are costly, especially on account of charges for transport.

It is expected that the isotopes in greatest demand will be radio-phosphorus  $P^{32}$  and the radio iodine,  $I^{131}$ . The following information about the preparations of these two isotopes available is given by the United States Atomic Energy Commission:

**Phosphorus<sup>32</sup>**—Half-life 14.3 days. Beta radiation 1.71 mev. Supplied as the phosphate ion probably in the form of  $NaH_2PO_4$  in a solution containing 0.5 to 3 millicuries per millilitre. Chemical analysis is furnished with each shipment. Material will meet the following specifications:

Concentration	Greater than 0.5 mc/ml
pH	7-9
Total solids	Less than 10 mg./ml
Non-radioactive material	Less than 5 mg./ml
P (free)	Approximately 0.025 mg./mc added (Carrier-free material is available if desired)
C	Less than 5 mg./ml
Fe	Concentration so low that no precipitate is formed at pH 7-9

**Iodine<sup>131</sup>**—Half-life 8 days. Beta radiation 0.6 mev. Gamma radiation 0.367, 0.080 mev., and probably also 0.65 mev. (10-15%). Carrier-free, in neutral or weakly basic solution containing 0.3 to 2 millicuries per millilitre. Chemical analysis is furnished with each shipment. Material will meet the following specifications:

Concentration	Greater than 0.3 mc/ml
pH	7-9
Total solids	Less than 1 mg./ml
Ie inactive	0.1 mg./ml
Ie active	Less than $1 \times 10^{-4}$ mc/ml

The Medical Research Council will not accept responsibility for the accuracy of the statement as to radioactive content which will accompany each sample or for the freedom of the sample from toxicity.

The cost of the materials will depend on various factors, including the extent of the demand, but is unlikely in the first instance to be less than £1 per millicurie for  $I^{131}$  or 10s per millicurie for  $P^{32}$ .

While every effort must be made to utilize these therapeutic developments and possibilities to the full, there can be little doubt that, from the long-term point of view, the treatment of cancer and allied diseases is most likely to be advanced by the encouragement of tracer investigations, using both radioactive and non-radioactive isotopes. Materials for this purpose are also obtainable from the Medical Research Council, and at present, in view of the small quantities involved, no charge is being made.

*The need for extreme caution in the clinical use of radioactive isotopic tracers cannot be overemphasized.* The safety of non-radioactive tracers should recommend their use in clinical investigations.

### Dangers and Limitations of Radioactive Isotope Therapy

Certain dangers inherent in radioactive isotope therapy are becoming recognized, especially in the case of radio-phosphorus administered internally as inorganic phosphate. The most serious of these are possible injury to the reproductive organs, genetic damage, the induction of leukaemias and the hastening of the appearance of leukaemic conditions, and the production of malignant tumours. The leukaemogenesis and carcinogenesis including induction of sarcoma of bone, are likely to be delayed effects, with a long latent period of possibly five years and probably often longer. Accordingly, in the present state of knowledge it is usually unwise to employ radio-phosphorus in the treatment of patients of either sex in the reproductive period of life or in patients whose expectation of life exceeds five years.

In general, it must be concluded that therapeutic trials of radioactive isotopes should be limited to cancer and allied diseases and to polycythaemia vera. With rare exceptions radioactive isotope therapy should not be used in non-malignant conditions. Further, the opinion has been expressed that, in the present state of knowledge radioactive isotopes should in no case be used in the treatment of children suffering from non-malignant diseases.

Despite these limitations, there is an important field of investigation of the therapeutic applications of radioactive isotopes. At first it will be necessary to develop techniques and to confirm and extend the results of the American workers while profiting from their experience. Subsequently it seems likely that the development of selectively concentrated organic compounds containing radioactive isotopes may be a promising line of investigation. Probably there will be an immediate though rather limited field for the use of external applicators containing sources of beta rays. Experience of the use of artificial gamma-ray sources, such as radio-cobalt (cobalt<sup>60</sup>) in radio-therapy is at present very restricted, but this is a matter for experimental development when adequate regular supplies become available.

All correspondence should be addressed to the Secretary Advisory Panel on the Allocation of Radioactive Isotopes for Clinical Research, Medical Research Council, 38, Old Queen Street, London, SW 1.

Iodine has been added to Part 1 of the Poisons List and to the 1st and 4th schedules to the Poisons Rules. The percentage limit in respect of codeine in the 1st schedule to the Poisons Rules has been raised from 1 to 1.5.

## INDUSTRIAL MEDICINE

## NINTH INTERNATIONAL CONGRESS OPENED

The Ninth International Congress on Industrial Medicine, which met from Sept 13 to 17, is the first to be held in Britain. Their Majesties the King and Queen are patrons. Congresses have been held under the auspices of the Commission Internationale Permanente pour la Medecine du Travail every four years, with intervals only during the two world wars, since the International Commission was founded in 1906 by Luigi Devoto in Milan. Lord Moran, P R C P, was in the chair and introduced the two speakers who delivered the inaugural addresses—the Rt Hon G A Isaacs, M P, Minister of Labour and National Service, and Mr T E A Stowell, President of the International Commission. Over 900 delegates from 44 countries had assembled in the Central Hall, Westminster.

Lord Moran started by saying that Their Majesties had sent a telegram expressing sincere thanks for the message of loyal greeting from the Congress and their best wishes for its success. Some of the delegates had come to learn what the others could teach them from their own particular experience and some to study the organization of an industrial medical service. We now had a health service available to all, we hoped presently to have a universal industrial health service for all who needed it. That service would come under the Ministry of Health.

They were all interested in the education of doctors who were going to take part in industrial medicine. Some thought the medical education of the undergraduate should include training for industrial work, but he could not agree. Medical education should be general and specialization should come later. He was surprised that so little attention was paid to the teaching of normal psychology in medical schools, but he disagreed with people who said that medical practice of that kind was inefficient only because of inadequate training. Often it was not lack of training so much as lack of imagination that prevented men from taking an interest in the psychology of the worker. It was necessary to study the minds of workers, and he gave as an instance the present shortage of nurses. Recent reports had shown that the nursing profession was receiving an inadequate number of recruits partly because of the working conditions, yet who was responsible for advising about those conditions but the medical staff? He then pleaded for more fundamental research to be done, and pointed out that the research worker who did not concentrate on finding the solution to a particular problem was nevertheless generally the man who solved our everyday problems. However, the Industrial Health Research Board had produced some 80 papers on industrial fatigue and hours of work, yet when the second world war came their conclusions had been completely ignored.

Turning to the question of incentives in industry, a problem much discussed at present, he thought that perhaps the best incentives lay not in wages but in human relationships, which he likened to the spirit that pervades a battalion in wartime. The industrial medical officer had a unique opportunity for studying group morale. Why had some men failed to adapt themselves to their surroundings? Medical officers must investigate and assess such factors as loss of interest and boredom. They must find the explanation for loss of harmony, for if men were contented you got increased production.

Mr G A Isaacs said that on looking through the programme of the Congress two things in particular had impressed him—the wide range of the diseases to be discussed and the fact that papers were not limited to strictly medical problems. Discussion was not intended to be narrow or academic. Medical officers working in special climatic environments—whether hot or cold or, as in Britain, sometimes hot and sometimes cold and always wet—would have the opportunity of exchanging views. Though appreciating the practical approach to the problems of industrial medicine shown by the Congress, he did not minimize the importance of the academic side. He knew how desperate the need was for more trained men and women. Industrial medicine had long received a good deal of attention in Britain. We had been first in the field in the development of industry and the first in dealing with the diseases that arose from it.

He strongly supported the formation of a national industrial medical service, and said that it was part of the Government's

policy. It depended on how soon they could get enough doctors. The mere appointing of doctors to factories did not make a service, for it depended much on specialized teamwork. At present the shortage of suitably qualified medical men was a grave obstacle. Facilities should be provided for postgraduate study, and he emphasized in particular the part that universities might play.

Mr T E A Stowell welcomed the delegates and displayed a scroll of greeting from the University of Paris, he also read a telegram from Professor E L Collis, who wished that the harvest the Congress would reap should be not British but international. Ours had been the first country to introduce legislation controlling conditions of work, and during the 36 years that he had practised industrial medicine he had noticed a considerable change of attitude to it on the part of employers. The Congress would allow the delegates to learn about each other's work and enable them to move towards the light of fresh understanding.

## Reports of Societies

JOINT MEETING OF AMERICAN, BRITISH, AND  
CANADIAN ORTHOPAEDIC ASSOCIATIONS

In spite of dollar difficulties the American, Canadian, and British Orthopaedic Associations for the first time held in Quebec in June a joint meeting. By the generosity of the Nuffield Foundation and the American Orthopaedic Association and other friends 13 of the younger British orthopaedic surgeons were enabled to attend the meeting and to undertake a magnificently organized six weeks' tour of North American centres. Those fortunate enough to attend have returned with a lively appreciation of Canadian and American hospitality and a determination that something should be done towards returning it on this side of the Atlantic in the not too distant future. Dr R I Harris (Toronto), President of the American Orthopaedic Association, Mr Alan S Malkin (Nottingham), President of the British Orthopaedic Association, and Dr Edouard Samson (Montreal), President of the Canadian Orthopaedic Association, presided.

## Joints

In a discussion on the treatment of slipping of the upper femoral epiphysis Dr S KLEINBERG advocated early elimination of the epiphysal plate by drilling and Dr BECKETT HOWORTH by bone pegging. Dr PHILIP WILSON (New York) advocated the Smith-Petersen nail for this purpose, and Dr ALBERT KEY (St Louis) considered that it should be placed as low and as far back as possible. Dr CLARENCE H HEYMAN (Cleveland) confirmed the good results of early epiphysal fusion. In late cases Drs ARMIN KLEIN, ROBERT J JOPLIN, JOHN A REIDY and JOSEPH HAMELIN (Boston) advocated osteotomy at the site of the epiphysal plate through an anterior incision.

Dr A B LE MESURIER (Toronto) reviewed developmental coxa vara, which was much less common than congenital dislocation of the hip and might be satisfactorily treated by intertrochanteric osteotomy, which was usually followed by speedy closure of the gap in the femoral neck. Dr WILLIAM T GREEN (Boston) thought that this treatment should be accompanied by an adductor myotomy in order to ensure sufficient adduction. In adult cases Dr ALBERT KEY had chiselled away the great trochanter without much further weakening of the adductors.

Dr ALEXANDER GIBSON (Winnipeg) reviewed 104 cases of vitallium-cup arthroplasty of the hip carried out through a Kocher's posterior approach. The results were good 55, satisfactory 21, poor 14, and unclassified 14. Dr PAUL C COLONNA (Philadelphia) doubted whether a posterior approach would allow the anterior tissues to be dealt with adequately, and Dr M N SMITH PETERSEN (Boston) expressed a similar doubt about the acetabulum. Mr H A BRITAIN (Norwich) demonstrated his method of ischio-femoral arthrodesis, saying that bony fusion was obtained in 84 out of 95 patients. He mentioned some of the complications, and other speakers emphasized the vulnerability of the sciatic nerve, especially in cases with flexion deformity.

Dr JUAN A FARILL described an operation for open reduction of cases of congenital dislocation of the hip otherwise irreducible. Wide exposure of the joint was followed by subtrochanteric femoral shortening and, if the acetabulum was shallow, by an extra-articular shelf. Some commentators thought the operation too drastic. Mr F C DURBIN (Exeter) advocated arthrography in congenital dislocation of the hip as part of the examination in every case, because of the importance of pathological anatomy both before and after reduction.

Dr W E GALLIE (Toronto) described a method of arthrodesis of the ankle-joint by the insertion of tibial grafts as mortises. Dr DALLAS B PHEMISTER (Chicago) and Dr THOMAS BEATH had carried out a similar operation on the knee and Dr ALBERT KEY (St Louis) in the sub-talar joint. Mr JOHN CHARNLEY (Manchester) had performed compression arthrodesis of the knee after the manner of Dr Albert Key and had found the junction to be solid as early as the twelfth day after operation.

In a discussion on arthroplasty of the knee it was emphasized that careful selection was imperative, then the results of the operation were usually satisfactory, though functional adaptation might take five years, after which the condition usually remained stable for a long time. Until the advent of penicillin gonorrhoeal arthritis had proved the commonest indication. Ankylosis from rheumatoid or tuberculous arthritis or from old osteomyelitis was unsuitable. The limb must have good musculature and the patient a stout heart.

Mr T J FAIRBANK (Oxford) had studied the changes in the knee following meniscectomy and had found radiological changes, described as a marginal ridge, flattening of the femoral condyle, and narrowing of the joint space. In the normal person the thickness of the articular cartilages diminished with weight-bearing and recovered in the intervals. Mr I S SMILLIE (Edinburgh) had interpreted as discoid menisci 28 among 1,300 menisci removed. He discussed the causes of "snapping knee." Tears were much commoner, particularly ones complicating a horizontal rift which resulted from the grinding action exerted by the condyles on the more primitive and complete type of discoid meniscus.

Dr ROBERT I HARRIS (Toronto) and Dr T HEATH (Columbia) had found that many cases of spasmodic flatfoot presented a developmental anomaly—namely, a talo calcaneal bridge which could be revealed by postero superior radiography.

#### Trauma

Dr EDWARD L COMPERE (Chicago) opened a discussion on aseptic necrosis of bone after injury by referring to the slow union after fractures in which an intermediary fragment of cortical bone is deprived of its blood supply. Dr DALLAS B PHEMISTER (Chicago) discussed the results of aseptic necrosis of cancellous bone as exemplified by the femoral head. In such cases he had tried to accelerate revascularization by inserting tibial grafts in addition to threaded wires. Results were encouraging and were confirmed by Mr JAMES PATRICK (Glasgow) who combined Smith-Petersen nailing with grafting.

In a paper on the treatment of cervical fractures and fracture-dislocation, Dr WILLIAM A ROGERS (Boston) advocated the use of skull traction, supplemented in most cases by wire fixation of the involved vertebrae and grafting with bone chips. Twenty of twenty-one grafts underwent fusion in a period averaging four months. In the treatment of fracture-dislocation of the pelvis, Mr F W HOLDSWORTH (Sheffield) combined traction with the use of an encircling sling. The results were much better if the sacro-iliac joint had escaped dislocation.

Dr E HOWARD WILSON (Columbia) advocated screws and when necessary, plates as the treatment of choice in fractures of the shaft of the femur or for fixation after limb-shortening operations. Full movement was restored within six months. Dr E C JAMES (Hamilton) had found the use of external pin fixation a solution of many of the problems presented by infected war wounds with compound fractures. Mr W GISSANE (Birmingham) described the organization of an accident service as exemplified by the Birmingham Accident Hospital.

#### Neuro-orthopaedic Conditions

Professor STEN FRIBERG (Stockholm), in an anatomical investigation of lumbar disk degeneration, had confirmed the instability between vertebrae bordering a ruptured intervertebral

disk. Degenerative changes were most pronounced in the anterior part of the disks except the fourth and fifth, in which they were mainly posterior. One or other of these two disks showed protrusion in 11 of 100 spines of patients of various ages examined after death.

Dr K G MCKENZIE and Dr F P DEWAR (Toronto) had found that in scoliosis with paraplegia the scoliosis was usually severe and congenital, though sometimes idiopathic or, less often, due to poliomyelitis, rickets, or neurofibromatosis. If there were no early response to conservative treatment the paraplegia called for surgical division of the dura mater.

Mr F G ST CLAIR STRANGE (Canterbury) showed the result of a case of ulnar and median nerve defect, too great for end-to-end suture, in which he had bridged the median nerve defect with a pedicled nerve graft from the ulnar nerve, with a success equal to the best which could be expected from end-to-end suture.

Dr MARY S SHERMAN (Chicago), speaking of oestrogens and bone formation in the human female, referred to the hypercalcaemia associated with ovulation and the formation of an egg-shell in certain birds. This was preceded by intramedullary hyperossification, and was not a parathyroid function, the ionized blood calcium being unaltered, but could be produced by oestrogens. Post-menopausal osteoporosis might result from deficiency of these and be relieved by their administration.

## Preparations and Appliances

### A MOUTH-SHIELD FOR USE WITH THE BRONCHOSCOPE OR LARYNGOSCOPE

Dr JOHN HALLAM of Liverpool, writes. Injury to the upper teeth or alveolus is at times an almost inevitable mishap with the use of a bronchoscope, and rather less often with a laryngoscope. The more common accidents are, in order of frequency: (1) the dislodgment of loose teeth, especially deciduous teeth which are about to be shed; (2) chipping of the enamel of one or more of the upper teeth, usually an incisor, or dislodgment of crowns and inlays or even, on occasion, sound teeth; and (3) in edentulous patients, bruising or crushing of the upper alveolar margin by the bronchoscope as it is moved around the bronchial tree. While many of the accidents in the first group can be avoided by pre-operative dental treatment, this procedure is not always possible, nor, occasionally, is it in the best interest of the patient. For example the extraction of all slightly loose teeth in a patient who is found on bronchoscopy to have an inoperable bronchial carcinoma is only going to add to his burden.

To circumvent these mishaps a series of mouth-shields of various sizes and shapes, suitable for all classes of dentition, have been made. They are constructed from soft plastic into

Mouth shield for edentulous case

Reverse side of mouth-shield

which is embedded stainless-steel gauze. This gauze provides the necessary rigidity without bulk, and it increases the value of the buffer action by spreading the thrust of the instrument over several teeth. In case the shield itself should become dislodged (this eventuality has not yet been met with) a plaited silk ligature is attached to it and left hanging over the table, a small lead weight having been tied to the distal end. The shields may be sterilized by boiling and no injuries have been encountered since they were taken into use several months ago. Various shapes and sizes can be made and dental impression trays have been found useful for the making of suitable models. It should be possible for any dental laboratory to make them.

## Correspondence

### Scientific Medicine in Britain To-day

SIR,—There is much to command assent in your leading article on "Scientific Medicine in Britain To-day" (Sept 4, p 479), but I ask your permission to make two critical comments thereon, one historical and the other on general grounds.

Historically, your survey, though of necessity brief, is presumably intended to be comprehensive. It tells the reader that "fifty years ago clinical medicine was for the most part a subject separate from or unconnected with physiology," and that clinical work of scientific quality was being pursued "almost in isolation for twenty years" by Sir Thomas Lewis. May I therefore bring to your notice the achievements of the British school of clinical neurology, a school now some eighty years old and in continuous and fruitful scientific activity since its foundation? It has made contributions of fundamental quality to the anatomy and physiology of the nervous system, to pathology, and to nosography.

I do not propose to burden your pages with the record of the labours of this school, but the present generation has seen in the field of the physiology of sensation the work of Henry Head and his collaborators, of Holmes, and of Trotter and Davies, in the analysis of cerebellar function and of the cortical representation of vision that of Holmes, and in the study of the basal ganglia that of Kinnier Wilson. In the field of nosography its clarifications, clinical and pathological, are scarcely less noteworthy.

It has to be admitted that all this has been the work of practising clinicians, amateurs if you will, carried on with neither salaries nor subsidies, nor with that growing multitude of secretarial and technical assistants that now seems to be essential to even the most modest of medical research projects. Nevertheless, a survey of the field of scientific medicine that omits mention of it can hardly be regarded as balanced or as giving a true perspective, while the quotations from your article that I have given show that it is inaccurate and historically unjust. It is not necessary thus to seek to enhance the distinction of Lewis's work, the brilliance and quantity of which stand in no need of the fictitious background of a scientific void in clinical medicine which, with more artistry than accuracy, you have created for it. Secondly, I submit that your article betrays, both historically and philosophically, an artificial conception of the relations between clinical medicine and physiology, between physicians and physiologists. They are not separable in the naive fashion you propose.

The few instances I have given of the work of clinical neurologists constitute discernments and rational formulations of dynamic properties of the human organism elicited in the course of clinical work, and to imply that they are parts of physiology but not of medicine and that those who did this work are rather physiologists than physicians is surely no more than a misleading linguistic exercise seeking to produce distinctions where they do not exist and to make medicine appear as a derivative of physiology. I submit also that "habits of deep thought and scholarly reflection" are not to be thought of as the necessary fruits of a deliberate consecration to "research discipline." Is there no discipline of accurate observation and logical induction in medicine apart from research?

In brief, I suggest that your article places too much reliance upon planning and takes too little cognizance of the human material being planned for over its head. The theme you adumbrate is indeed of vital importance to such future as British medicine can now look forward to under its new regime of external organization, but it surely needs to be more profoundly contemplated and more clearly expounded if it is to bear fruit.—I am, etc.,

London W1

F M R WALSHE

### Globin Insulin—A Criticism

SIR—In your issue of July 24 (p 191) Dr G M Wauchope published a paper strongly extolling globin insulin, one daily injection, as the ideal treatment for almost all insulin cases. Professor D M Dunlop and Dr J B Donald (Aug 14, p 352) from Edinburgh have criticized her optimism. I would add my

fairly wide experience of globin insulin to support their opinion.

Dr Wauchope states that globin insulin is identical in its delayed action with Dr Hagedorn's original protamine insulin (retard, 1935). This I am sure is true and makes me ask her how it can act for 24 hours without grave risk of hypoglycaemia, which I have too often seen before the midday meal or in the afternoon, with a heavy relapse of the diabetes at night. Animal tests too show that the delay in its action is very little different from ordinary soluble insulin. The Danes and Hagedorn were factual enough to know in 1935 that their new "retard" insulin (= globin insulin) was an impossible treatment given once a day to severe diabetics, and they gave it in the evening with soluble in the morning. Globin insulin once daily, as Professor Dunlop says, is good for mild insulin cases—any type is almost equally good—but P Z insulin is probably better. But without full detail I merely want to record my opinion that one morning dose of globin insulin is a poor treatment for severe diabetics.—I am, etc.,

London W1

R D LAWRENCE

### Streptomycin and Insulin

SIR—A patient who has both diabetes mellitus and pulmonary tuberculosis has made two comments on his streptomycin treatment. 1 While taking streptomycin (0.5 g twice a day intramuscularly) his insulin requirements, to avoid glycosuria with the same diet, have increased from 55 or 60 units daily to 77 units daily. 2 Whenever he has injected ordinary insulin and streptomycin within an inch or two and within a few minutes of each other he has had severe pain between the sites of injection, but if kept further apart in time or in space neither is unduly painful. The severe pain is burning "like a hot iron," and prevents sleep. One evening the streptomycin dissolved in 15 ml of 1% procaine was given in proximity to insulin. The pain appeared, but not until about five hours later, and he had no more sleep that night. Publication of this may save others trouble pending further observations.—I am, etc.,

St Leonards on Sea

E A WOOD

### Renal Complications in Diabetes Mellitus

SIR—In their discussion of renal complications in diabetes mellitus in your issue of July 24 (p 194) Drs W R Gauld, A L Stalker, and A Lyall make no mention of the condition of the renal arteries in their post-mortem cases. When an attempt is made to correlate hypertension with pathological changes in the kidneys the investigation has little value without a thorough examination of the renal arteries, in view of the work initiated by Goldblatt on the hypertension produced by ischaemia of functional renal tissue from constriction of the renal arteries. I have seen three cases of the syndrome which the writers describe, one in a young subject. While all showed conspicuous intercapillary glomerulosclerosis, this lesion was inconspicuous measured against the bore of the renal arteries, which in all cases was at some level reduced to a microscopic slit from severe atherosclerosis. There was also universal gross narrowing of the branches in the pelvis.

If a Goldblatt mechanism obtains in those cases, much more weight must be put on a lesion in the renal arteries than one at glomerular level. It is to be hoped that any future publication on the subject will give due prominence to this point. I have read some of the references which the authors cite. None mentioned the condition of the renal arteries.—I am, etc.,

Regina Saskatchewan Canada

NORMAN G B McLETCHE

### Diabetic Coma

SIR—Professor D M Dunlop and Dr J B Donald (Aug 14 p 352) are harsh in their criticism of Professor R H Mick's valuable article. The high death rate in the UK in cases of diabetic coma is attributable to the insufficient insulin dosage recommended in British textbooks. How many deaths has Professor Dunlop had in his last 54 cases of diabetic coma?

Surely no physician should treat diabetes without the facilities for blood sugar estimation? If he has not such facilities

# world-wide local ANAESTHESIA

'Anethaine' was introduced in 1941. The times were grievous, and the need for local anaesthesia was of overriding urgency. 'Anethaine' was brought into immediate prominence and subjected to the severest of tests. 'Anethaine'\* provides a valuable advantage in that it is many times more powerful than procaine or cocaine and is yet of lower relative toxicity, since it may be used in much higher dilution. Today, applications for 'Anethaine' range from major operative cases to the relief of pains common to everyday accidents and affections—and in another sense, from England to the Antipodes.

\*ANETHAINE brand (Amethocaine hydrochloride)  
For surface infiltration and spinal anaesthesia.  
A new lozenge form for throat and larynx prior to  
instrumentation is now available.

GLAXO LABORATORIES LTD., GREENFORD MIDDLESEX ENGLAND

## An advance in Penicillin therapy . . .

### 'AVLOPROCIL'

#### Procaine-Penicillin Oily Suspension

'Avloprocil' contains the procaine-salt of Crystalline Penicillin in oily suspension and offers important advantages to both doctor and patient —

- Therapeutic blood levels of penicillin maintained for at least 24 hours
- Effective penicillin therapy achieved with a *single daily injection*
- Administration comparatively free from irritation and pain

10 c.c. vials (300,000 units of penicillin per c.c.) Singly and in boxes of 5

## NEW TREATMENT FOR ASTHMA

Relatively free from the undesirable cardiovascular and other side-effects of adrenaline injections, 'Neo-Epine', a recently-developed homologue of adrenaline, possesses marked advantages in the treatment of bronchial asthma. It may be given sublingually or by oral spray. The drug has been found to be an effective substitute for adrenaline. Superior to ephedrine, it does not cause sleeplessness.

### 'NEO-EPININE'

ISOPROPYL<sup>NOV</sup>ADRENALINE SULPHATE

Tablet brand compressed products for sublingual administration each containing 20 mgm in bottles of 25 and 100. Spray Solution containing 1 per cent of drug in bottles of 10 cc. Literature and samples on request.

## Painless INTRAMUSCULAR INJECTIONS

e.g. of **PENICILLIN, LIVER EXTRACTS, ARSENO-BENZOLS, BISMUTH, etc.**

Many substances create some pain on intramuscular injection. Novutox injected at the same time will prevent this pain.

Most substances are compatible with Novutox, which is also non-destructible to penicillin during the time that the latter is undergoing absorption.

Mixtures with Novutox should be made *immediately before use ONLY*

## NOVUTOX

*Self-Sterilising*  
*Local Anaesthetic*

Each cc. of Novutox 2% contains 0.02 gm ethocaine hcl - 0.00002 gm epinephrine and 0.00002 gm capryl hydrocupreinatoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

### Prevention of Dental Caries

SIR—A masterly review of the distribution among the tribes and nations of the world of dental caries, and possible causes, by H H Neumann, of New York, was published last year as a letter in the *Lancet* (1947, 1, 806). He concluded that "the factors commonly blamed, such as mineral deficiencies, fluorine deficiency, poor dental hygiene, inadequate sunshine, constitutional factors, vitamin deficiencies, and overuse of starch and sugar in the diet, have little effect on endemic dental decay, and do not explain the peculiar geographical distribution. The consistency of the food, the table manners of the people, and the extent to which cutlery is used are far more important. The disuse of odontoporus which leads to dental caries can be prevented and to some extent treated by restoring to the teeth their proper work of chewing by adding sufficient toughness to what we eat." Earlier in the letter he suggests that the addition of some hard breadcrust (old Swedish or Italian type of bread) to the daily diet would suffice to maintain fairly good teeth with a reasonable low caries incidence.

What a simple way of saving an enormous amount of suffering and waste of money on tooth-brushes and powders, stoppings, extractions, and artificial dentures. Teach, in the mothers' clinics, to use as little as possible cutlery and soft food and give children tough crusts to chew. Lady McIlanby has laid great stress on dietetic factors. Can she lend her authority to the spread of the use of toughness in the diet?—I am, etc.,

LEONARD HILL

### Pioneers of Social Medicine

SIR—Sir Arthur MacNalty's generous review of my Heath Clark Lectures (Sept 4, p 476) gives me an excuse for commenting on the publication itself. With rare exceptions, of which a course by a professor emeritus of epidemiology and vital statistics is not one, academic lectures do not pay the cost of publication. Sales merely slightly reduce the bill to be defrayed from trust funds. I should therefore have supposed that in these days of austerity it would have been sufficient to issue the lectures in paper wrappers and to put them on sale at less than the cost per copy of publication. That any member of the public, other than a lunatic at large, would be tempted by a green cover with gilt lettering and crest to pay 12s 6d for a booklet which can be read through in a couple of hours is, to me, incredible. However, the disgust with which I look at this ugly little trollop is partly due to injured vanity. Even medical statisticians dream of having readers other than personal friends—I am, etc.,

Loughton Essex

MAJOR GREENWOOD

### Genu Valgum

SIR—In discussing the aetiology of genu valgum in Mr H A Brittain's excellent article (Aug 21, p 385) omission is made of a simple mechanical observation. I have had opportunity of observing many infants who have developed knock knee as a direct sequel to tibial bow legs. Many babies have bow legs at birth due to a cramped position *in utero*—often an example of a large foetus in a small mother. If these cases are followed up during the first two years it will be found that as spontaneous correction of the bow legs takes place in the lower half of the tibial shafts the tibial arc straightens and the ankles diverge, resulting in genu valgum.

During the transition stage a familiar picture is seen comprising persistent femoral anteversion, genu valgum, slight tibial bowing, and an intoed gait. The intoeing is due to the combination of the femoral anteversion and the internal rotation of the tibial bow legs. With natural development the femoral anteversion and the tibial bowing are usually corrected, with resultant disappearance of the intoed gait. The residual deformity is now the knock knees, with prominent internal femoral condyles and widely separated malleoli. We must not

### Reactions to Intravenous Sclerotics

SIR—I should like to report the following acute allergic reactions following intravenous injection of venous sclerotics. I understand that such reactions are uncommon, out of many hundreds of injections of varicose veins by sodium morrhuate (usually 5%, occasionally 10%), I have seen only these two.

**Case 1**—A man aged 64, nervous type and given to alcohol, was given 1.75-ml doses of sodium morrhuate (5%) over a period of 14 months (1935–6). In 1943, owing to recurrence of the veins, he was given further injections of 5% sodium morrhuate as follows: Sept 18, 2 × 1.75 ml; Oct 16, 2 × 1.75 ml. Half to one hour following the last injection he had the following symptoms: tingling of hands and feet, marked generalized itching, and collapse. This was regarded by me when reported as a nervous reaction aided by the fortification with alcohol before and after the injection, but he reported the same symptoms after the next injection. I therefore ceased using sodium morrhuate and gave him five subsequent injections, 3 ml of 10% sodium salicylate, without any after effect.

**Case 2**—A man aged 48 was given 24 injections of sodium morrhuate. The first was of 2 × 1.75 ml (5%), the subsequent ones being increased owing to the poor reaction to 2 × 1.25 ml 10% sodium morrhuate. These were given over a period of three years. He was not a particularly nervous type, nor particularly given to alcohol.

At the 24th injection he had the following reaction. Within 10 minutes he complained of tingling and itching in the hands and genitals. This increased after he had gone half a mile, and the itching became general and intense. He collapsed about a mile away, fortunately outside the ambulance station. He was taken to hospital, where I saw him 50 minutes after the injection was given. He had an acute generalized urticarial rash. Pulse was good. He was given an injection of 0.4 ml of liq adrenaline hydrochlor, and in two hours he had recovered.

Fourteen days after this reaction he was given an intravenous injection of 4 ml of 30% sodium salicylate and had a precisely similar allergic reaction, together with a feeling of swelling in the windpipe, this time in the consulting-room, where he had been kept. He was given the same treatment and he recovered in the same manner.

Acute allergic reactions following the intravenous injection of sodium morrhuate are uncommon. In the second case reported above the recurrence of an allergic reaction after changing to a completely dissimilar chemical substance must be even rarer—I am, etc.,

C E TAYLOR

### Fibrositis

SIR—Surely the aetiology and pathology of fibrositis and its clinical manifestations were settled and agreed on long ago—since the days when Rabagliati termed it "perimyositis rheumatica," and Gowers gave it the name of "fibrositis," and Stockman, fully 50 years ago, expounded the whole matter, and demonstrated microscopically the lesions in the white fibrous tissue and how best to feel the nodules when the skin is lubricated with vaseline. But it is needless to say more. Thousands of doctors are satisfied, and have been for many years, as to what fibrositis is, its cause, its alleviation if not cure, and its treatment. It is an important and interesting subject, but a thing quite apart from the lesions of an intervertebral disk—I am, etc.,

St Andrews

R O ADAMSON

### Fibrositis and the Weather

SIR—Whatever fibrositis is or is not, it is real enough to those who suffer from it. Many are able to tell with monotonous regularity when the weather is about to change for the worse. In Palestine, with its rapid succession of dry heat and damp cold in certain regions, it was common, often in the form of headache. The Arabs, who are presumably tough and uninhibited, would often ask for aspirin for this condition.

The point has been raised before, but I still do not know, and no pathologist has told me, why an old wound aches in damp weather. I have often thought that the fibrositic tissue was in some way structurally impaired, similarly to scar tissue. If the effects of weather are so striking in this condition it

should not be difficult to experiment with fibrositic subjects in artificial climates. At the risk of being tedious I suggest that the effects are not due entirely to temperature, pressure, or humidity, but that the electrical changes in the air should also be considered.

The awareness of temperature and climatic changes seems to vary much from one person to another. Some quite suddenly discover that they are much too hot or chilled right through. In my student days I sometimes started work in a warm room, to be discovered by a relative some hours later chilled right through, with the fire out, and quite unaware that this had happened until I was bundled into bed and warmed up. I cannot concentrate so well now—I am, etc.,

Hadley Wood Herts

G C PETHER

### Cerebral Aneurysm

SIR,—Cases of ruptured cerebral aneurysm are, one under stands, by no means rare, yet sufficiently so that I do not recollect in 20 odd years of practice being reasonably convinced of being in the presence of one. Nevertheless I have lately seen two which were confirmed at necropsy. Both were men about 30, both had recently been discharged from the Forces, one having seen active service in the Tank Corps and the other in the Infantry, which prompts one to speculate how far the vigorous training called for in both these units led to these aneurysms bursting when they did, and causing one to wonder why, under the stress and strain of training and active service, they did not do so before.

I was called out at midnight to the first case and found him in bed complaining of the sudden onset of violent occipital headache and of loss of power in his legs. He had also been sick. He felt rather better next morning and had regained the use of his legs, but the headache persisted. BP was normal, Kernig's sign was positive, and there was some nuchal rigidity. He survived two or three weeks in hospital, but eventually succumbed. His wife informed me that his original attack had come on during sexual excitement.

In the second case the patient had on the previous evening been to a regimental reunion and had collapsed in the street just after leaving. He admitted that he took "a few beers," but denied any excess of conviviality. He also complained later of occipital headache and vomiting, and within a day or two he had a positive Kernig's sign and nuchal stiffness. He refused to go to hospital and was away from work for six to eight weeks, when he returned to work apparently quite well. One morning about four months later, just as he was cycling past a hospital on his way to work, he collapsed off his cycle and was already dead when picked up or died shortly after being admitted.

As stated above, post-mortem examination confirmed the presence of ruptured cerebral aneurysm in both these cases—I am, etc.,

Hove

G L DAVIES

### Shipping the Sick

SIR,—Shipping of the sick on a British ship is a nightmare. May I give this example? I managed to send a girl missionary to England—? tuberculous caecum (two outside surgical opinions)—for domestic, financial, and climatic reasons. I might have been trying to send a case of plague home. I gave full case notes, chest radiograph, sputum reports, and the almost certain guarantee that she would require no medical attention. Finally, when I was lucky enough to guarantee that if she required medical attention there was a missionary doctor on board who would take full responsibility, she was accepted with bad grace. Comparisons are odious, but the difference on American ships is astonishing. Friendliness, delight at receiving case notes, and willingness to accept responsibility have been my experience. Unfortunately these ships do not use British ports.

If shipping companies want "protection," it should be possible to have a medical board to decide the suitability and circumstances of a patient to be sent home. The laity of the shipping companies cause the initial obstruction. And again I know of cases where the doctor has not disclosed that the patient has been ill—in the patient's interest—and they have gone as ordinary travellers. Personally I am nervous of taking

any risk and prefer to face the music, and have the remark as in the above case, "I'm not having shore doctors push their responsibilities on to me."

British men and women abroad should be entitled to expert opinion and treatment in their home country if thought advisable, and the courteous and correct handing over of a case history should not be considered as a "shifting of responsibility"—I am, etc.,

Colombo

B M NEWAY

### Stainless Steel Wire

SIR—I was most interested in the paper by Messrs A Lawrence Abel and Alan H Hunt (Aug 21, p 379) and should like to add a few observations in support of this excellent suture material. Two years ago Mr Alan Hunt initiated me into the use of stainless steel wire, and I have employed this suture for every abdominal section since. The unverified total is between five and six hundred cases, and I have nothing but praise for stainless steel wire.

In a Hunterian lecture recently published in the *Lancet* (July 17, p 85) I drew attention to the importance of early ambulation in the avoidance of post-operative complications. There is no doubt that stainless steel wire enhances the confidence of a surgeon and his team in getting patients out of bed the day after operation. Nothing but good has accrued from this, and the incidence of fatal pulmonary embolism in my cases in the last two years has been one case. This occurred in a woman who had multiple abdominal sinuses following an operation some two years previously and in whom the ultimate diagnosis was actinomycosis. It was interesting to note that she was too ill to be given ambulant treatment after operation, and a post mortem examination demonstrated a large clot in the pulmonary artery arising from the internal iliac veins, presumably of septic origin. There have, however, been a number of cases of leg thrombosis and/or pulmonary infarction successfully treated by heparin, in spite of early ambulation. This is mentioned because early ambulation, though helpful, is not the final answer in the prevention of phlebo-thrombosis and thrombo-phlebitis.

The test case for stainless steel wire was a recent one in which a straightforward total hysterectomy was followed by paralytic ileus. The patient's abdomen was enormously distended for 14 days, and the suture line was put to a test which I feel sure that no other material than stainless steel would have withstood. Any surgeon who uses catgut must sooner or later have a burst abdomen, no matter how carefully he ties his knots or spaces his interrupted sutures. In 1944 I performed a myomectomy on a member of the WAAF and sewed the rectus sheath with interrupted catgut. For no reason at all she burst her abdomen on the fourth day, and examination of the suture line revealed a necrosis of the sutures, which were incompetent to hold the tissues in place. Such a case is unlikely to occur with stainless steel wire when properly employed. On one occasion my wound has been taken down by another surgeon for an acute appendicitis developing some weeks after hysterectomy. He reported a sound, clean, first-intention healing of the original incision.

I have been asked on many occasions what would happen to the stainless steel sutures if the patient were to receive diathermy treatment or x-radiation. This is a question that ought to be answered.

Finally, I can only say that since I have employed stainless steel wire the instance of wound sepsis has decreased almost to vanishing point, and that any sepsis which has occurred I think can be fairly blamed upon the use of catgut to tie subcutaneous bleeding points—I am, etc.,

London W 1

JOHN HOWKINS

### Prevention of Venereal Disease

SIR—I have only just seen the *Journal* of Aug 21, and the letters (p 400) from Drs W B Laing and F R Curtis commenting on mine in your issues of July 31 (p 269) and Aug 7 (p 313). May I reply in one letter?

The fact of the existence of VD is a side issue to the main problem. If this disease could be entirely removed, or an infection immediately cured, a devastating illness would be thankfully banished. But if injustice, exploitation, disloyalty, and unchastity remain in the relation of individual human beings

to one another, or in the relation of State and people, the root of mental and bodily ill still exists. Countries which have practised that State regulation of prostitution recommended for our adoption by Dr Laing have turned from it not only because its uselessness in controlling V.D. is apparent but because the proved results—degradation of men and women, and especially of youth, appalling injustice, the tentacles of vested interests, the traffic in women and children, the militancy of the whole system against justice and love—have finally revolted the human spirit.

The scope of law should be strictly limited, especially in relation to sexual morality. But there is a tendency to-day in every country and in every political party to formulate legislation on what seems expediency rather than on strict principle. Then very soon laws are made which apply to particular classes of persons only, regulations which no one can keep track of, undermine rather than clarify law, and the power of the executive continues to grow.

I know enough of the work of V.D. and other clinics to appreciate and respect the enormous care that has always been taken to attract and retain the confidence of sick persons. I know also that the medical profession does not need legal sanctions to force it to keep the confidence reposed in it. Whatever the law, or lack of it, as I said in my previous letter, no doubt all concerned with V.D. patients will do all in their power to maintain confidence and keep information confidential. But with the removal of the statutory requirement of confidence they may not be able to do so. Even with this requirement a doctor can be called to give such evidence in a court of law, but this is very rarely done. The power to keep medical information confidential seems to be rapidly going in this country as Sir Ernest Graham-Little has pointed out, and it has gone in some countries.

Under Defence Regulation 33B the legal requirement of confidence ceased to apply with regard to certain persons known or alleged to have V.D. I did not hear that any member of the medical profession objected to giving evidence or to sending his medical reports on such V.D. patients, whose confidence, presumably, was as worthy of respect as that of any other patient. The law allowed and required such information, and it was given. If the law allows breach of medical confidence in relation to V.D. patients at public clinics, as it now does, it will in a very short time require it for certain classes of persons, and the medical and allied professions will be in a very difficult position. The patient loses not only some guarantee of medical confidence but also a very real protection against the casual or malicious gossip of acquaintances.

The World Health Organization has plans for various World Conventions relating to health and disease. There is much that is good and necessary in these proposals, though the tendency to mass compulsion of all sorts is apparent. Certain of the V.D. proposals, particularly, seem to be in many respects dangerous to justice and liberty. They provide for an international "black list" of certain defaulters, compulsory hospital detention, investigation of suspected or alleged sources of infection, and so on. The past and present history of such attempts, on a smaller scale, shows that officials (medical and police) are thus given almost unlimited power over certain individuals known, suspected, or informed against, or whose alleged way of life suggests that V.D. may be present. Very little thought is needed to appreciate the acute danger of such power, both to those who have it and those who have to submit to it, or to see that confidence must be non-existent in such proposals.

The World Health Organization has unique power, in that any resolutions it may adopt come automatically into force for all member States unless objection is registered within a certain period. My Association considers that the public should know as much as possible about the national and international legislation to which it is, or is being, committed. With regard to V.D., for instance, why should the public be misled by the Minister's continuing propaganda and advertisements guaranteeing secrecy and confidence? It cannot now be guaranteed, however much the staffs of the public clinics may and do desire to keep that confidence. A test case is bound to arise, and then it will be known if, in Dr Curtis's words, 'secrecy is now so strongly entrenched by custom in the minds of the public and clinic staffs that a statute is unnecessary to buttress it

Many people in every country are appalled by the denial and disintegration of justice and of individual freedom. It is this Association's business to seek to know and to fight for justice in its own specialized but fundamental work, and that it is doing—I am, etc.,

KATHARINE B. HARDWICK,

General Secretary  
The Association for Moral and Social Hygiene

London S.W.1

SIR—All your correspondents on both sides err in regarding venereal disease as a moral problem. Venereal disease is a social problem. It is caused by the failure of so-called civilized society to settle its problems other than by war, to pay its young people a wage adequate to enable them to marry at the physiological age for marriage, child-bearing, and parenthood, and to provide its young people with homes for themselves and their children.

If a young man is doing a job which is necessary to the community he is entitled to the wage and to the house which will enable him to support a wife and family. Without his children to carry on his job when he is done society will not survive.

Attempts to prevent venereal disease by continence or by condoms are alike futile and the result of muddled thinking. Like all therapeutic measures they do nothing to remove the cause of the problem and so do nothing to prevent its perpetuation—I am, etc.,

Tavistock Devon

JOHN SLEIGH

SIR—This hoary quinquennial is always productive of the larger prejudices, moral, medical, social, humanitarian and religious, but in the interests of accuracy the more extreme examples cannot be allowed to pass unchallenged.

That provision and knowledge of prophylaxis control, or other measures increase or decrease promiscuity and/or numbers of infections is admittedly debatable, but to affirm, as does Dr R. C. Webster (Sept 4, p. 499), that "there is no method of prophylaxis which affords any significant degree of protection" is contrary to all accepted evidence. The 1922 Trevethin Committee's findings on this point have never been seriously challenged.

It all depends on what is considered significant, but that the medical and general staffs of all the Allied Forces would have permitted a not inconsiderable portion of their manpower, preventive organization, accommodation, and equipment in every theatre on land and sea throughout the war and after to have been wantonly wasted in a futile endeavour seems, to say the least of it, somewhat improbable. Venereologists are truly "incredulous," not least of alleged use of P.A.C.s, etc., by their patients.

That closure of brothels in Cairo and elsewhere resulted in a diminution in the incidence of disease is an accepted fact. The old B.A.O.R., in which I had the fortune to serve i/c the Connaught Hospital, Wiesbaden, in 1927 and 1928, and the French Army in 1930 somewhat to its surprise, made the same observation, the latter over an experimental year in a typical garrison city, Metz. (It should always be remembered that peacetime conditions are not comparable with war.)

To allege, however, that supervision, where it existed, was everywhere cursory and futile is an exaggeration. Such control could and did eliminate the grosser macroscopic, sometimes condylomatous, varieties of disease, and where conscientiously exercised, as it was within the observation of venereologists in many areas of the B.E.F. in 1939 and 1940 by the French Army and civilian medical services, was a great deal better than none at all, and to its efficacy may be attributed at least in part the relatively low incidence of disease in the B.E.F.

Most will agree with Dr Robert Forgan's (July 31, p. 269) melancholy reflection, and will regret that so far from having any further powers, so cogently demanded by Dr Laird recently, even the timid wartime advance of 33B has now been withdrawn—I am, etc.,

London S.W.1

W. H. DICKINSON PRIEST

SIR—Colonel P. F. Chapman (Sept 4, p. 498) asks how I protect my hands against infection in examining venereal patients. The answer is obvious by using rubber gloves and/or antiseptics. As adults we are aware that there are certain differences between the conditions of professional examination and coitus. The contacts of examination are brief, the examiner is presumably sober and is not excited,

he exposes certain defined areas, and has technical skill in the removal of his gloves, which protect a wide margin about his fingers. In coitus the exposure is to relatively prolonged frictional contact under pressure the areas involved are freely secreting, the individual is emotional and not necessarily sober, and if chemicals are used they are applied at an indeterminate later time. A condom protects a very limited area: chancres of the root of the penis or the scrotum are not rare.

The question whether an effective method would be opposed on moral grounds is irrelevant—we are asking if such a method does in fact exist. If the application of calomel cream after coitus would prevent syphilis I do not see that it has any moral bearing. That is a non-specialist opinion, and as such of little more or less value than my views on mathematics. Similarly Colonel Chapman's statements in his letter on morals generally and on social anthropology of sex have no special value other than as individual opinions. They have no value in deciding whether effective prophylaxis of venereal diseases is possible.

In fact, as distinct from theory, I know that elaborate plans for prophylaxis in the Services were a failure. I have visited many prophylactic centres, seen the busy traffic of issuing outfits, and like any other venereologist heard all the tales that begin, 'It can't be that, I used...' To the enthusiasts I would say, Ponder a little on the mechanics of coitus, and add to the result of these meditations common-sense knowledge of the actual circumstances of promiscuity, physical and mental, and it will be clear that prophylaxis is not practicable—I am, etc.,

Todinorden, Lancs.

R C WEBSTER

SIR—Dr R C Webster (Sept 4, p 499) suggests that "the views of a doctor in his professional capacity as to the value of marriage certificates and chastity as an ideal have no special value." I wish to make it clear that I entered into this correspondence principally to protest at the introduction of the question of morality by Dr G L Russell (July 31, p 268), and to reject as of no practical value Miss K B Hardwick's platitude (p 269) that "the only sure prevention of VD is chaste living."

The figures provided by Dr A Michael Critchley (Sept 4 p 499) illustrate the value of controlled brothels in Egypt. When the Cairo brothels were in bounds there is no doubt that the majority of exposures to infection occurred there, yet only 52% of the VD cases were infected in this way. That the number of men having intercourse outside of brothels was small is confirmed by the drop in the apparent exposure rate to one-tenth which followed their being put out of bounds. The corresponding fall in incidence of VD, however, was only one-quarter. From these figures it is obvious that in the Cairo area it was very much safer to have intercourse in a controlled brothel than elsewhere.

I object, however, to the assumption that Egypt provides a satisfactory example of the controlled brothel. Doubtless an attempt to enforce chastity in military personnel will have a certain degree of success in the prevention of VD in countries like Egypt where, by putting certain areas out of bounds, the opportunity for promiscuity is reduced almost to nil, but I think Dr Critchley is wrong in attributing the drop in promiscuity, and especially the improvement in "the general conduct, morals, and morale of the troops," entirely to the fact that in October, 1942, the brothels in Cairo were put out of bounds. The victory at El Alamein, (October, 1942) and the glorious advance of the 8th Army which followed should, I feel, be given some of the credit—I am, etc.,

Edinburgh

W B LAING

SIR—The recent series of letters on this subject has been a source of considerable interest, if only to observe the generations-old conflict of ideas voiced again in yet another form: abstinence v biological urge, prophylaxis and education v increased promiscuity, the licensing and medical inspection of brothels v their increased use and subsequent suppression, sympathy v punishment for the sufferers, and notification v the liberty of the subject are the basic chords, but the whole has become hopelessly entangled and indeed has always been so. The tragic part of the whole business is that so diverse are the views which are so sincerely held by their proponents

we appear to have a number of agencies all professing to work to the same ends yet quite unable even to consider working together. As a result nothing really worth while is done and we muddle on as before.

A study of the issues involved leads at any rate to one inescapable conclusion which, once realized, holds out real hope for the future. That is that case-finding is the only essential for venereal disease prevention. If all persons infected with venereal diseases were placed under treatment it would not matter in the slightest how monastic or promiscuous persons were, or how hygienic or otherwise their sexual behaviour. Neither, strictly from the VD standpoint, would it matter whether brothels in any form existed or not, or whether, or no troops should be discouraged from visiting them. Granted this thesis—that case finding is the kernel of the problem—here is the common denominator for the agenda of the National Society for the Prevention of Venereal Disease, the Association for Moral and Social Hygiene, the Central Council for Health Education, and all similar bodies interested in these diseases, not to forget the Ministry of Health and the doctors working in the clinics.

Here then is the means—for the necessity of case-finding cannot be gainsaid. The members of all the above bodies must unite on this to solve the one remaining conflict, that of notification v personal liberty, and in this will be found scope for all to produce a formula which is satisfactory to the British way of life. The thought of notification and a "venereal police" is quite abhorrent to the majority, but existing methods are inadequate for their purpose. The contact slip as used in the clinics achieves some success for known contacts, but what, if anything, should be done, either individually or collectively, for those that are unknown is the real crux of the matter and deserves the attention of all. Let case finding be the number one aim, but at the same time the propaganda of these societies and bodies should still preach their favourite subsidiary methods. As long as these are kept subservient to the main issue there can be no great disharmony.

In order to quell any criticism that it is easy to write generalizations I will conclude with a practical suggestion. In recent years propaganda trains, such as the penicillin train and the atomic energy train, have toured the railway stations of the country. Let the above mentioned educational bodies together sponsor a VD train with the accent on case finding. Within it the individual factions can each also advocate their chosen auxiliary measures.

I apologize, Sir, for coming in at the end of what is now a very lengthy correspondence, but hope you will permit this contribution to be published before blowing the final whistle—I am, etc.,

London W 2

R R WILLCOX

\* \* This correspondence is now closed—ED B M J

### Shortage of Nurses

SIR—Dr N Strang, in his recommendations (Sept 4, p 500) for nursing recruitment, has placed in a nutshell what the Working Party has failed to do in a volume. May I add that not only should the student nurse be given a professional salary on qualification but that during her training she should be given the same status as any other university student. To suggest that inflexible rules and regulations, still so prevalent to-day are necessary for hospital discipline does, in my opinion, reflect darkly on the ability of those charged to maintain it.

If the same methods are used to attempt to attract girls to the nursing profession as are regularly used to draw them to under-manned industries, then it seems to me that those qualities of initiative and responsibility—the hall-mark of any profession—will gradually disappear from the nurse as they have done from the industrial worker since the standard methods of recruitment were started at the time of the Industrial Revolution—I am, etc.,

Birmingham

JAMES R CROSS

SIR—Dr N Strang's programme (Sept 4, p 500) for dealing with the chief menace in the hospital world to-day is refreshingly constructive. It omits, however, practical suggestions for dealing with a major cause of reluctance to enter the nursing life—viz, the attitude of parents who become experts in steering their girls to other channels of employment not without reason, though their thoughts are often camouflaged. They are conscious of the too high sickness rate that is common during training years. This factor in shortage has never received due attention.

Even this year a young nurse in a London teaching hospital can lie in a sick-bay for some eight weeks with no care at a higher level than that of a young R M O who tells the parents not to fuss as all tests are negative. When at last convalescence is arranged and three weeks at the sea are over the girl can return to duty and be put on 'night' with no further investigation. Further breakdowns need surprise no one. Such handling of nurses' health is not good propaganda, but it seems nobody's business to raise the general standard of care for the rare and precious human material that our hospitals lack—I am, etc

Northwood Middlesex

ESTHER CARLING

## POINTS FROM LETTERS

### Low Back Pain

Dr F W INMAN (Wallasey) writes: In my time low back pain has been consistently called lumbago, and has been blamed on the liver not turning uric acid into urea. The treatment has been always by large doses of salicylates and colchicum. With experience in a busy surgery extending over fifty years I have found this treatment sufficient in most cases. True there are residual cases, which can be recognized by their failure to respond, but these are a comparative rarity and no doubt should be investigated with a view to surgical treatment. In the old days when gout was more often seen the connexion with severe lumbago would be more easily recognized. In one of his books Dr Thomas Inman, of the old Royal Infirmary, Liverpool, gives a most graphic account of an attack. As port medical officer he had been on board a ship in the Mersey and had strained his back getting on board. Whilst being rowed back to the landing stage he took an opium pill, and the coxswain read the label. Climbing up the rope ladder he cricked his back again and had to be helped up. On the stage he was unable to speak, and the men, at the direction of the coxswain, ran him up and down the stage thinking that he was suffering from opium poisoning.

### Dangerous Talc

A correspondent writes: I was interested to read in the article in the *Journal* of June 5 (p 1077, *et seq*) and in the annotation on page 1090 that it has been discovered that talc can cause granulomata. Not so many years ago I was lying in a sanatorium bed suffering from pulmonary tuberculosis, and every day I was religiously washed, rubbed with spirit, and dusted with scented talcum powder. I remember wondering at the time whether talcum powder was likely to cause silicosis, because every time I turned over in bed I inhaled a shower of it, blown up from between the sheets. I used to console myself with the thought that the Superintendent would not have allowed its use if it had been harmful. What simple faith one had in those days! However, I made an uneventful recovery in spite of the talc. But in view of these recent disclosures I think doctors might well discourage its indiscriminate use by enthusiastic nurses, especially where such a delicate thing as a tuberculous lung is concerned.

### Fourth Attack of Mumps

Dr W W NEWTON (Birmingham) writes: I have seen a young woman aged 17½ years in my surgery this morning with a swollen and tender left parotid gland and general headaches and malaise. Her temperature was normal. In May, 1946, she had typical mumps, and also twice in childhood during school attendance. To have mumps four times in about 12 years is surely very unusual and worth reporting.

### Spraying Fruit

Dr JAMES FORREST (London W 1) writes: Always partial to raw and cooked fruit, I ate my first basket of strawberries with relish, but an hour later I was overcome by a feeling of nausea so strange as to be mystifying. Not until a fortnight later did I eat other strawberries which occasioned a nausea that three hours later was followed by vomiting so violent and instantaneous that before I could reach the lavatory my stomach emptied itself. Assuming that the reaction was a recent allergy it was without apprehension that I ate red currants and raspberries, but similar symptoms were induced and suggested that some poison introduced by spraying the trees or the fruit after it was picked was responsible, which was confirmed by the fact that from a garden in which no chemical is used I ate similar fruit in large quantities without the slightest ill effect. So prevalent are gastric disturbances this summer that according to the Press some councils have issued circulars warning the public against consuming fruit or vegetables that have not been thoroughly washed. But more informative and more valuable would be the opinion of general practitioners upon a subject that is so far-reaching in its significance.

## Obituary

S W WHEATON, M.D., F.R.C.P.

Dr Samuel Walton Wheaton, a former medical officer of the Ministry of Health, died on Sept 5 at the age of 86. He was born in Salisbury in 1861, and received his medical education at St Thomas's Hospital, where he held appointments as house-physician, resident accoucheur, and as demonstrator of physics. Before becoming a medical student he had acted as personal secretary to Sir Henry Fawcett, the blind Postmaster General, and he continued these duties while a student, frequently studying for long hours at the House before taking Sir Henry back to his home near Vauxhall after late night sittings. Nevertheless he won the Mead Medal for Practical Medicine and gained a *proxime accessit* in the Murchison Scholarship.

Dr Wheaton qualified in 1886, obtained the London M.B. with honours in medicine and forensic medicine in 1887, and proceeded M.D. in 1888. He took the D.P.H. of the English Conjoint Board in 1889, was admitted M.R.C.P. in the same year, and elected F.R.C.P. in 1906. He was a councillor of the Royal College of Physicians from 1926 to 1928. Early in his career his interests lay in diseases of women, and he obtained the post of physician to the Royal Waterloo Hospital for Women and Children, and contributed articles on obstetrics and gynaecology to clinical societies and medical journals. He maintained this interest throughout his long life, contributing a chapter on maternity and infant welfare centres to the *Practitioner's Encyclopaedia of Midwifery and Diseases of Women* which was published in 1921.

At the end of the last century Dr Wheaton gave up his hospital appointments and became a full-time member of the public health service, first as an inspector of the old Local Government Board and later as a medical officer of the Ministry of Health on its formation. He was a member of the Epidemiological Society before its fusion with other societies to form the Royal Society of Medicine. He served as medical assessor to the Miners' Welfare Committee and took an active interest in, for example, the provision of pithead baths. For more than thirty years Dr Wheaton was engaged in Governmental inspections and inquiries directed to the control of epidemics and to the improvement of local public health administration, claiming to have visited nearly every village in Wales on foot in connexion with his work. More than twenty of his official reports have been published.

He was a keen naturalist, with a great interest in geology in its relation to water supplies. Painting was his lifelong hobby, and he had considerable skill, his colour sense being developed to an unusual degree. He never failed to bring back from his tours of inspection a number of watercolour sketches, later to be interpreted in oils. He exhibited frequently in the exhibitions organized by the Ministry of Health and other civil service art clubs and associations. Dr Wheaton retired from the Ministry of Health in 1927, but was extremely active to within a few days of his death. His two sons are both members of the medical profession.

Dr J Alison Glover writes: Greatly to my advantage I shared a room with Dr Wheaton for the last six years of his official career. He was one of the great age of Victorian sanitary reformers, retaining alike the side-whiskers and the morning tail coat of that era, and might have passed for the typical father of 1900. Before I knew him I thought his appearance formidable, but he proved invariably kind. He was a great pedestrian, walking to the office and back daily from Streatham Hill, and his unrivalled acquaintance with the details of the sanitary circumstances of this country was due not only to his retentive memory, keen observation, and long experience but especially to his rule of making all his inspections on foot. He seemed to have walked over every rural district in Britain. He was a competent geologist, and his knowledge of almost every gathering ground had a lasting influence on the policy guiding the water supply of this country with its particular emphasis on the purity of the source, an emphasis which has been wholly beneficial. By the time I knew him his views were naturally somewhat conservative, but to the last he was a ways

ready to adopt well-proven new methods, and he had been an early pioneer in the introduction of the maternity and child welfare service. On by-laws, particularly those relating to conservancy, nuisances, and offensive trades, his was the final opinion. I shall not forget the impression he made upon a deputation from the Ministry of Health of Czechoslovakia which visited this country soon after the first world war. It was my duty to conduct them during their visit, when they met many of the prominent public health authorities. None impressed them more than Dr Wheaton, with whom they were frankly delighted. Dr Wheaton's death removes one of the last of the great environmental reformers, whose valuable services to his country have scarcely received the recognition they deserve.

#### A W GILL, MD, FRCP

Dr A Wilson Gill, one of the leading members of the profession in North Staffordshire, died in the North Staffordshire Royal Infirmary at the age of 60 on Aug 30. Alexander Wilson Gill, a native of Edinburgh, was educated at the Royal High School there and at Edinburgh University, where he graduated in 1909. After qualifying, Dr Wilson Gill became a house-surgeon and later house-physician at Addenbrooke's Hospital, Cambridge, and subsequently resident medical officer at the City Infirmary, Birmingham. In 1912 he proceeded MD, his thesis being on the study of auricular fibrillation using electrocardiographic methods, which were still in the early stages of their development. In the same year he went into general practice as an assistant to the late Mr Reginald Alcock at Hanley and subsequently was in partnership. During the 1914-18 war Dr Wilson Gill was in charge of the medical arrangements at a poison gas factory for two years before being commissioned in the RAMC and serving in France and Belgium with the 53rd Field Ambulance. In the closing stages of the war he was regimental medical officer to the 6th battalion of the Dorsetshire Regiment. During the war Dr Wilson Gill became increasingly interested in neurological problems. He experimented with hypnotherapy, and subsequently published a number of papers on the problems of neurosis. At the same time he maintained his interest in cardiology and took charge of the cardiographic department of the North Staffordshire Royal Infirmary. His connexion with the infirmary began with his appointment as an honorary medical registrar there, and not long afterwards he became one of the assistant physicians and later physician to the hospital. He also served on the honorary staff of the Burslem Haywood Hospital and for a period of eight years the Staffordshire General Hospital. Until the time of his retirement he was in charge of both the neurological and cardiological departments of the North Staffordshire Royal Infirmary. He took the MRCP in 1927 and was elected FRCP in 1944, by which time he had been in consulting practice for some ten years. He was at one time president of the North Staffordshire Medical Society, and was president of the Staffordshire Branch of the British Medical Association in 1935-6. As a young man he was a keen tennis player, and later in life he fished for trout regularly in the River Dove. The sympathy of his many friends and colleagues will be extended to his widow, formerly Miss Edith Mary Johnson, of Congleton.

#### THOMAS GWYNNE MAITLAND, MD, DPhil

Dr J C Matthews writes. The obituary notice of Gwynne Maitland (Aug 28, p 445) revived my memory of my first meeting with him in a BMA committee-room in the middle 'twenties. It is of a courteous English gentleman with an encyclopaedic knowledge of affairs in general and of all branches of medicine in particular. He was already the much-valued medical superintendent of the Cunard Line, and we met as members of an *ad hoc* committee appointed to consider the status and training of the ship doctor, Courtenay Lord was secretary to the committee. At that time Maitland was *au fait* with all the problems, his own company and several others had already instituted very necessary reforms, leading to the establishment of a definite and worthy branch of the profession. His contribution to the work of the committee was therefore outstanding. I have not seen Maitland during the war years, previously we met from time to time,

usually on trains, and his wide interests made him a delightful travelling companion.

Dr Fergus Armstrong writes. Dr Gwynne Maitland was known to many doctors for his genial personality and great help in transatlantic voyages. For five voyages he was surgeon in the *Franconia* for the cruise round the world, and in America he was truly a real British ambassador. Thousands of Americans who voyaged with him found him a great gentle man, and always spoke of him in the highest terms. Deck tennis owes him its first rules, and he was an excellent exponent of lawn tennis and deck tennis. I first met him in 1915 when he was medical director of Lady Paget's Hospital of the Serbian Relief Fund in Serbia. He surrendered the hospital to the Bulgarians and was a prisoner of war for six months in Serbia with our unit. In those days he was the life and soul of the hospital and kept all our spirits up during those trying days. Medical travellers across the Atlantic will miss his guidance, for he was a great help to all the profession who went to America.

Dr STANLEY DUNN METCALFE who died in May this year at his home in Newcastle-upon-Tyne, aged 63, was born in Sunderland and trained at the Durham College of Medicine, graduating MB, BS in 1907. After serving as junior and senior house-physician in the Royal Victoria Infirmary, Newcastle-upon-Tyne, he became assistant to the late Dr Neil Maclay at Wallsend for some two years. He spent the next eighteen years in general practice in Newcastle, after which he became a regional medical officer with the Ministry of Health. In that capacity he worked in Middlesbrough, Preston, Darlington, and finally in Newcastle. In 1946 he suffered from a coronary thrombosis but was able to resume his duties, and he carried on until the day of his death from a further thrombosis. A man of retiring habits and high ideals, Dr Metcalfe was beloved by his patients, whom he served so well. An omnivorous reader, his chief interest was in archaeology, his holidays were spent in visiting cathedrals and churches in Britain. To those who had the privilege of knowing Metcalfe in his home life his loss comes as a heavy blow. For it was especially there that his quiet and sound philosophy was most apparent, and it was there that his valuable advice, culled from his vast store of human experience and understanding, was so readily available to all who sought it. Many young students and professional men will have in their minds a picture of Metcalfe sitting in his chair against the background of the books he loved, and will recall the memory of one who enjoyed life in his own quiet way and gave of his best to others.

Dr HENRY FRANCIS BELL-WALKER died in July at his home in Cape Colony at the age of 72. Entering Guy's Hospital with a scholarship and graduating in 1903, he proceeded MD three years later. He was successively clinical assistant and medical registrar at Guy's Hospital, resigning the latter appointment in 1907 to go to South Africa to a practice at Bedford. He served with the SAMC in the first world war and went through the South West African Campaign, during which time he wrote *A Doctor's Diary in Damaraland*. In 1931 he left Bedford and went to farm in the Kat River valley, but still found time to practise medicine among the natives and poorer people of the district. Throughout his farming life he kept in close touch with his profession and in 1938 was awarded the Hamilton Maynard Medal for his article on the prognosis of heart disease, which was published in the *South African Medical Journal*. He was a member of the Medical Council for five years, and, being particularly interested in medical education, was appointed an examiner. He again served with the SAMC from 1941-5, and was appointed physician specialist at the Military Hospital, Durban. Latterly Henry Bell-Walker became convinced of man's dependence upon the soil and of the impossibility of building a sound civilization without true husbandry. Briefly his articles of faith were "There is no life without food or food without life. There is no health without good food. There is no good food except from good earth. There is no good earth without good care. There is no good care but what you give yourself." And it is as he was in this last phase of his long life that those who knew him best will always remember him.

Dr EMRYS DANIEL OWEN died at Swansea Hospital on July 21 at the age of 50. He had been engaged in general practice at Neath for the last twenty-two years. Emrys Owen entered Aberystwyth University in 1916 after winning the premier entrance scholarship. After two terms he was called up and spent two years in the Army and Flying Corps. From

1919 he continued his medical studies at the Welsh School of Medicine in Cardiff, taking the BSc in 1921. He completed his medical training in 1923, and was one of the first four students to qualify from the Cardiff Royal Infirmary, which had by then been recognized as the parent hospital of the Welsh School of Medicine. His career at Cardiff was a distinguished one. He gained the Alfred Hughes gold medal in anatomy, and the gold medal in obstetrics and gynaecology. He held several resident appointments at the Royal Infirmary, and the surprising thing is that he did not continue in hospital work, his record and abilities were such as to assure him a future as a consultant on the staff of the hospital. He chose, however, to go into general practice, first as an assistant in Maesteg and then at Neath, where he spent the happiest years of his life, being loved not only by his family but by all his friends and patients. Emrys Owen was a good doctor and an outstanding personality. He was always so humble, and those of us who realized his capacity appreciated his unostentatious ways and manner of expression. He was an active member of the executive branch of the Swansea Division of the BMA, a member of the local medical committee for Glamorgan, and a past president of the Neath Rotary Club. He was a founder member of the Neath Medical Society, and just before his death he was appointed to the West Glamorgan Hospital Management Committee. His death has meant a great loss to the profession, and above all to his widow and two young sons, to whom the sympathy of all his colleagues will be extended.—R D O

Dr DAVID ALEXANDER MURRAY who died suddenly on Aug 9 while on holiday at Dornoch, his birthplace, will be sadly missed both in his native Sutherlandshire and by his patients and friends in Helmsley, where he had practised for many years. He graduated at Edinburgh University in 1925, but before even matriculating he had during the 1914-18 war the unusual experience of leaving school and getting to the French front. He was still so young that when the authorities noticed his age he was sent home to start school again. He was one of the best of country doctors, with a good knowledge in medicine applied with much common sense. He knew the family and background of each patient, and every one of them he treated as a friend. When winter in the dales was too severe for normal transport he would set off cheerfully by tractor, sledge, or on foot. His main recreations were racing and golf. At the former he declared he was always in the end successful as a punter, at the latter there was no doubt about his excellence. He learned his golf in his native Dornoch, and there are many stories of his battles royal with champions visiting there, battles in which he by no means came off worst. His friends will miss greatly his cheerful good humour and his unselfish ways. It is difficult to think that we will not meet him again by the bedside or on the links, and that affectionate memories are all that remain.—D R C

Dr ONG CHONG KENG was murdered on the evening of Aug 31 while answering a call to attend a sick person. Dr Ong was one of the most prominent members of the medical profession in Penang. He was born there in 1904, and was educated at the Penang Free School. He took his MB, BS at Hong Kong University in 1928, and returned to Malaya to practise. He had always taken an active part in the public life of the settlement, where he served as municipal commissioner. He was nominated to the Advisory Council of the Malayan Union in April, 1946, and continued as a member of the Federal Legislative Council after its formation. He was also a member of the Federal Executive Council. He had been President of the Penang Rotary Club, and served as an officer of the Chinese Company of the Penang and Province Wellesley Volunteer Corps. Last year Dr Ong attended the United Nations Organization Educational Conference in Nanking as a delegate from Malaya. Dr Ong had been a member of the British Medical Association for many years.

Dr BERNARD RAYNE PARMITER died in Wimborne Cottage Hospital, of which he was a medical officer after a short recurrence of a previous illness on Aug 19, at the age of 62. Educated at Dover College and Guy's Hospital, he qualified LRCP MRCS in 1911 and graduated MB BS in the following year. He held house appointments at Guy's Hospital, the Evelina Hospital for Sick Children and at the Brompton and Lewisham Hospitals. During the 1914-18 war he served as a captain in the RAMC for four and a half years in Egypt, Gallipoli, Macedonia, Palestine, and after the armistice in Constantinople and Asia Minor. Coming to Wimborne as a partner in general practice in 1920 he took a keen interest in many aspects of the life of the community, and became greatly loved by the people around for his personal

qualities as well as for his professional skill. He was public vaccinator for the Wimborne Rural Area, medical officer to the Wimborne Infirmary, and medical officer to St Christopher's Children's Home. There the children watched eagerly every Tuesday afternoon for Dr Parmiter's car. The shyest of them would be put at ease, and laughing and talking to him in a very few minutes. He entered into all their fun and will be sorely missed. The older children will always carry with them memories of his unfailing kindness. Outside his purely professional work he found time to be a member of the town council and its chairman in 1928-9, a churchwarden of Wimborne Minster, and president of the local branch of Toc H. His happiest recreation and interest was perhaps the Boy Scouts, of which he was the district president. For many years he spent part of his holiday in camp with them, and had always been closely associated with the movement. Last April he was invested on behalf of the Chief Scout with the gold medal of merit for forty years' outstanding service. He served on the Dorset Panel Committee and Dorset Medical Service Committee for many years until stricken in 1945 with the malady which was later to cause his death.

## Medico-Legal

### DAMAGES AGAINST AN ORTHOPAEDIC SURGEON

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

A mishap with plaster-of-Paris resulted in an action in the Manchester Assize Court being settled for £7,000 damages against Mr Ian Douglas Kitchin, a surgeon of the Lancaster Royal Infirmary. Dr Cecil Gould, a general practitioner, was also sued but exonerated. The evidence showed that the father of a boy of five consulted Dr Gould about the child's knock-knees and was referred to Mr Kitchin. The boy was admitted to the infirmary, and the father was assured that the operation would be a perfectly simple manipulation of the knees and an encasement in plaster. After a week the boy came home. He was obviously distressed and was awake during the night, constantly kicking out with his right leg. The father found the toes were white and the foot cold, and saw signs of gangrene. Dr Gould examined the boy and said that he could not do anything about the leg, the plaster was tight but it was the surgeon's job, it would be all right and he would return in the morning. He paid another visit the next day and said the plaster seemed to be tight. When the father returned from work the boy was in agony, and he cut away part of the plaster to give him relief. Next day he took him back to hospital. Mr Kitchin was very angry that the plaster had been touched and said that the child must come in again. Four days later the new plaster was covered with blood. For a month after discharge the child was taken regularly to the hospital as an out-patient and about four new casts were put on the leg. The father by this time was in something like despair and asked that Professor McMurray be called in, but Mr Kitchin would not agree, saying, "You need not worry when I have made a mistake I will let you know." In the result the boy's foot was paralysed and the calf muscle practically wasted away.

Mr Henry Poston, a Manchester surgeon, said that the cause of the boy's condition was the tight fitting of the plaster. If the plaster had been removed on the day after the boy first returned from the hospital there would have been no disability but if it had been left until the next day a pressure ulcer would have formed. Mr D L Griffiths, an orthopaedic surgeon, said that there was a strong chance that the right leg would have to be amputated.

Mr Kitchin giving evidence, said that when the boy was first discharged there was a chance for his recovery. After seeing the leg later he realized that some damage had been done but thought that a good useful leg could still be obtained. He agreed with the judge's suggestion that the seed that had brought about the present condition of the boy had existed on his return to the hospital three days after his first discharge. The treatment when the boy was in hospital for the second time was to allow the abscess to drain and continue if the drainage was clear. Asked whether it would not have been a good idea to try penicillin earlier, he replied that at that time he would not

use it until he could locate the abscess, but now it was used blind. When the boy was brought back with the plaster cut there was no sign of an abscess, though he thought one was present. Later it presented on the lateral side of the calf. When he first saw the boy he thought an osteotomy for knock-knee would be necessary, but after some months there was an improvement and only manipulation was required. When the boy was discharged for the first time he was perfectly well and did not complain of pain. Some restlessness during the night was caused by the rubbing of the plaster at the top of the leg. The circulation was good and the plaster not tight. When his father brought him back he was obviously ill; he was flushed and had a well-marked bronchitis. The toes of the right leg were slightly swollen and faintly bluish. The leg which was swollen had been under tension, but Mr Kitchin could not find a cause for the pressure. Some damage had been done at that time, and he decided to watch the leg. There was some blistering of the leg after removal of the plaster, a not uncommon happening. He could not recall the father pressing for a second opinion. When the child was brought back as an in-patient for the third time the foot was reinfected.

On entering judgment for the amount agreed, the judge remarked that it was always an extremely painful matter to try a case against a professional man. Everyone, with the best will in the world, made mistakes. There had been no complaint here of lack of professional zeal. Mr Kitchin might have formed an erroneous conclusion but there was no scintilla of suggestion of any sort of unethical conduct from start to finish. Obviously Dr Gould, against whom the case had been withdrawn, was not in any way responsible. He had nothing to do with the operation, the plaster, or the treatment. The boy had come out of a first-class hospital with the highest specialist treatment and technical skill, and he would have been taking a very grave risk if he had taken the law into his own hands and done anything with the plaster.

## Universities and Colleges

### UNIVERSITY OF CAMBRIDGE

George Fulton Roberts, M B, B Chir, and Norman Boyne Finter, M B, B Chir, have been appointed University Demonstrators in Pathology for three years from Oct 1.

Raymond Seidehn, B M, B Ch, has been elected to an Elmore Medical Research Studentship from Sept 1.

### UNIVERSITY OF GLASGOW

George Lightbody Montgomery, T D, M D, Ph D, F R F P S, has been appointed to the St Mungo-Notman chair of pathology, associated with the Royal Infirmary, Glasgow, in succession to Professor John William Stewart Blacklock, M D, F R F P S.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

At a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow held on Sept 6, with Professor Geoffrey B Fleming, president, in the chair, the following were admitted Fellows of Faculty *qua* Physician: J B Cochran, J E A David, M M Desai, T Jack, P MacArthur, R C MacGillivray, W G Manderson, R A Peebles Brown, N Sher. The following were admitted Fellows of Faculty *qua* Surgeon: J T S Buchan, R W Busschau, T L Chapman, G L Clark, J R Hutchinson, J D Joubert, A B Kothari, W S Mack, Pearl A I MacLeod, A M Porter, W Rankin, C J Slight, W B Stirling, A E Wilkinson, R B Wright.

The Nurseries and Child Minders Regulation Act recently received the Royal Assent, and in Circular 143/48 the Ministry of Health draws the attention of local health authorities to their duties under the Act. From now on all premises used as day nurseries must be registered, and persons who take children under 5 into their own homes for the day and receive payment for this must also be registered. Local health authorities may lay down conditions about the administration of day nurseries, and about the number of children who may be received in a daily minder's home. Similarly requirements about medical supervision of the children and the taking of precautions against infectious disease may be imposed. This new duty of local health authorities will stand referred to the health committees recently set up under the National Health Service Act.

## Medical News

### World Medical Association

At the meeting of the General Assembly of the World Medical Association in Geneva last week Dr Charles Hill, Secretary of the British Medical Association, was made President Elect for the year 1949-50. The General Assembly will meet again in London in the autumn of 1949.

### W M A Bulletin

Dr Morris Fishbein, Editor of the *Journal of the American Medical Association*, has agreed to serve as Editor of the *W M A Bulletin* which will be published in the U S A.

### Higher Pay for Student Nurses

The Nurses and Midwives Whitley Council has agreed that student nurses, pupil assistant nurses, and pupil midwives employed in the National Health Service shall receive increased allowances from Sept 1. A first-year student in general training receives £200 a year plus dependants' allowances and meals on duty. The cash allowance is £100 (an increase of £30), and the emoluments are valued for superannuation at £100. Dependants' allowances are 10s a week for an adult and 5s for the first child. Payment in the second year of training is £210 plus £5 on passing the preliminary examination. In the third year it is £225. The first year rate for pupil or probationer assistant nurses is £200 plus dependants' allowances, and for the pupil midwife who is a State-registered nurse £230 (not State registered, £205). The provisional rate for the post registration student nurse with three years training is £230 in the first year. Students living out are allowed free meals on duty, uniform and laundry in addition to their allowances. A special committee is considering the remuneration of student mental nurses and student nursery nurses.

### Rockefeller Travelling Fellowships in Medicine

The Medical Research Council announces that Rockefeller Travelling Fellowships in Medicine for the academic year 1948-9 have been awarded as follows: Dr K W Donald, Medical Professional Unit, St Bartholomew's Hospital, London; Dr L P R Fourman, Nuffield Department of Clinical Medicine, University of Oxford; Dr R H Girdwood, Department of Medicine, University of Edinburgh; Dr A Isaacs, Department of Medicine, University of Sheffield; Mr A I S Macpherson, Department of Surgery, University of Edinburgh; Dr H B Stoner, Department of Pathology, University of Sheffield; Mr S F Taylor, Department of Surgery, Postgraduate Medical School of London.

### Study of Tumours

The Committee on Pathology of the American National Research Council has appointed a subcommittee on oncology with the following members: Dr Shields Warren (chairman), Dr Baldwin Lucke, Dr Fred Stewart, Dr Harold Stewart, Dr Arthur P Stout, Dr Milton C Winternitz, Dr Howard T Karsner (chairman of Committee on Pathology, *ex officio*). Brig-Gen Raymond C Dart, Director of the Army Institute of Pathology, is co-operating with the committee and making the institute's facilities and resources available and is providing office space for the permanent secretary. The aims of the subcommittee are: (1) improvement in the teaching of oncology, (2) dissemination of information on oncology to clinical pathologists, students, and teachers of oncology, (3) the establishment of criteria for diagnosis of tumours, (4) the simplification of terminology by recommending a single term for each tumour and listing separately the appropriate synonyms.

### Oculist to the Princess Royal

Mr B W Rycroft has been appointed oculist to H R H the Princess Royal.

### Mental Health of Children

To help the development of an international organization for the mental health of children an office has been opened at 30, West 58th Street, New York City, to which inquiries should be addressed. The following officers of the council have been elected: Dr Leo Kanner, Johns Hopkins University School of Medicine (president), Dr M Tramer, editor of the *Internationale Zeitschrift für Kinder psychiatrie* (vice-president), Dr Ernest Harms, editor of the *Nervous Child* (acting secretary).

### Wills

Sir George Francis Blicher, of Frensham, Surrey, late of University College Hospital, left £44,424. Dr John McMyn, of Kirkcudbright, left £3,852. Dr John Gutch, of North Walsham, Norfolk, left £53,474.

# FOCUS ON SULPHADIAZINE

for

EVIDENCE accumulated during recent years indicates that Sulphadiazine is probably the most highly esteemed sulphonamide throughout the world

Its effectiveness against many bacteria, its low toxicity, and the ease with which blood-levels can be maintained following its use all establish a preference for Sulphadiazine

The physician will find Sulphadiazine Lederle the dependable sulphonamide in the majority of the commoner bacterial infections

Sulphadiazine Lederle is available in bottles of 100 and 1000 0.5 Grm scored tablets

## ASTHMA

- aborting  
the night attack

In a new paper (Practitioner, June, 1948, p 468 9) the author attributes to 'Franol' the power of suppressing nocturnal asthmatic attacks in patients who otherwise are awakened regularly in the early hours. Under 'Franol' treatment they gain in weight and appetite and are much better fitted to lead a normal life.

The author states that, of the many preparations tested, 'Franol' gives the best results, through the actions of theophylline (on bronchial musculature), ephedrine (on nerve endings), and 'Luminal' (centrally), there is probably some potentiation since the dose of each component is small.

One tablet at night and one on rising appears to meet most needs, and by effects are rare, the 'Luminal' in 'Franol' mitigates nervous tension and overcomes any individual intolerance to ephedrine.

## An Effective Analgesic

WHILE modern chemical research has evolved many and diverse analgesics the popularity of acetylsalicylic acid and its reputation for effectiveness remain. Nevertheless some physicians have hesitated to employ it owing to its tendency in certain conditions to irritate the stomach.

In Alasil however the desirable therapeutic effects of acetylsalicylic acid are maintained without the tendency to irritation by combining the acid with Dibasic Calcium Phosphate and Aloeol (Colloidal Aluminium Hydroxide) an effective gastric sedative and antacid. Thus Alasil helps to solve the problem of administering acetylsalicylic acid in an effective form even to patients with sensitive stomachs.

The advantages of Alasil have been well proved in practice. Experience shows that it can be prescribed with safety to patients of all ages.

Each tablet contains 5 grs Acetylsalicylic Acid 6 grs Aloeol (Colloidal Aluminium Hydroxide) and 14 grs Dibasic Calcium Phosphate.

## A new applicator for Volpar paste

A specially designed Volpar Applicator is now available for patients overseas where Volpar Paste is used instead of Volpar Gels and with equally satisfactory results.

Volpar preparations have been prescribed and used on an increasing scale throughout a decade and abundant evidence of their efficacy, acceptability and innocuousness has been produced.

Descriptive literature is available, on request

## COMING EVENTS

## Conference on Dust in Industry

The Society of Chemical Industry has organized a conference on Dust in Industry to be held at the University of Leeds from Sept 28 to 30. On Thursday, Sept 30, commencing at 9.30 a.m., the following papers relating to medical subjects will be delivered: 'Tetryl Dermatitis and Its Prevention,' by Professor W. M. Cumming and I. A. Brownlie, 'Recent Advances in the Study and Treatment of Silicosis,' by Professor E. J. King, M.A., D.Sc., 'Manganese Pneumonitis,' by Dr. T. A. Lloyd Davies, 'Arsenical Dust in Industry,' by Dr. A. M. Currie, M.A., 'A Positive Method for the Determination of Free Silica in Dusts,' by Professor A. L. Roberts, Ph.D., 'La Pénétration Pulmonaire des Toxiques Industriels. Exemple du Bioxyde de Manganèse,' by Le Doyen Professor R. Fabre, 'Cancer of the Lung and Cancer of the Nose,' by Dr. A. J. Amor, 'Idle Thoughts on the Pneumoconioses,' by Dr. E. R. A. Merewether, C.B.E., M.D., F.R.C.P., F.R.S. Ed. Attendance at the conference is free to members of the Society, who may obtain a set of preprints of the papers for 10s. 6d., others will be admitted on payment of £2.2s. for a set of preprints. Those wishing to attend are asked to advise the general secretary of the Society at 56, Victoria Street, London, S.W.1, as soon as possible, and also to state whether accommodation will be required. A special dinner will be held at the Queen's Hotel, Leeds, on Tuesday, Sept. 28, for those attending the conference. Tickets (price 21s. including wines) are available from Dr. J. E. Garside, at Leeds University, and early application is desirable.

## Smoke Abatement

The annual conference of the National Smoke Abatement Society will be held at Cheltenham from Sept. 30 to Oct. 1. The Minister of Fuel and Power, Mr. Hugh Gattskell, will address it. The Society will present a preliminary report on the survey of the sources and incidence of atmospheric pollution. Particulars may be obtained from the Society, Chandos House, Buckingham Gate, London, S.W.1.

## Royal College of Obstetricians and Gynaecologists

Dr. Emil Novak, Associate in Gynaecology, The Johns Hopkins Medical School, Baltimore, U.S.A., will deliver a lecture "On Certain Functioning Tumours of the Ovary" at the College (58, Queen Anne Street, London, W.), on Friday, Oct. 1, at 2.15 p.m. The lecture is awarded under an endowment by a Fellow of the College for "a lecture to be given every fourth year by an American gynaecologist of merit to cement more closely the bonds of friendship between the British Empire and the U.S.A., and as a token of gratitude for their help in the darkest hours of the World War." Admission is by ticket only, obtainable from the secretary of the College.

## William Blair Bell Memorial Lecture

A William Blair Bell Memorial Lecture will be delivered by Newell Willard Philpott, M.D., C.M., F.A.C.A., F.R.C.S. (Can.), F.R.C.O.G., Professor of Obstetrics and Gynaecology, McGill University, Montreal, Canada, at the Royal College of Obstetricians and Gynaecologists (58, Queen Anne Street, London, W.) on Saturday, Oct. 2, at 10 a.m. His subject is "Rhesus Factor Isoimmunization and Haemolytic Disease of the Newborn." Admission is by ticket only, obtainable from the secretary of the College.

## Hunterian Society

The annual party of the Hunterian Society will be held at Gunters Restaurant, 6, Stanhope Street, Park Lane, London, W., on Monday, Oct. 4, from 6 to 8 p.m. Fellows are asked to apply as soon as possible for invitation cards, price 15s. each, for themselves and their guests to Dr. Kenneth McFadyen, 74, Herne Hill, London, S.E.24.

## Postgraduate Lectures on Modern Therapeutics

A course of ten postgraduate subscription lectures on modern therapeutics will be delivered at the Society of Apothecaries of London (Black Friars Lane, Queen Victoria Street, E.C.) at 5 p.m. beginning on Oct. 18 and ending on Nov. 5. The fee for the whole course is £3.3s. single lectures 7s. 6d. Details will be published in the diary column of the *Journal* week by week.

## Annual Harveian Commemoration

The Royal College of Physicians of London will hold a dinner at the College Pall Mall East S.W., on St. Luke's Day, Monday, Oct. 18, at 7.30 for 8 p.m. The contribution payable by each Fellow is 10s. and those wishing to attend should notify the Registrar not later than first post on Oct. 1. The dinner is confined to Fellows and there will be no guests.

## SOCIETIES AND LECTURES

## Wednesday

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE—At 28, Portland Place, London, W. Sept. 22 3 p.m. 'The Surgical Treatment of Gastric Ulcers' The Bengue Memorial Award Lecture for 1948, by Dr. Paul Banzet.

## Friday

BIOCHEMICAL SOCIETY—At Department of Biochemistry The University, Sheffield, Sept. 24 11.30 a.m., 269th meeting. Papers will be read.

SURREY COUNTY MEDICAL SOCIETY—At Farnham County Hospital Sept. 24, 7 p.m. Clinical meeting.

## APPOINTMENTS

Drs. E. Y. Laurent, C.M.G., A. E. De Chazal, O.B.E., and J. M. Cure have been appointed Members of the Legislative Council of the Colony of Mauritius.

Alexander James Smith McFadzean, M.B., Ch.B., M.R.C.P., has been appointed Professor of Medicine in the University of Hong Kong.

Dr. McFadzean, who is 34, qualified in 1936 at Glasgow University and took the M.R.C.P. Lond. in 1946. He is at present lecturer in medicine at Glasgow University.

Brian Brendan Hickey, M.A., B.M., M.Ch., F.R.C.S., has been appointed Director of Surgery to the Morriston Emergency Hospital, Swansea.

Mr. Hickey graduated in 1935 after training at Oxford University and the London Hospital. For the last two years he has been Surgeon to the Iraq Government. He recorded a case of blast injury in this *Journal* in 1945 2 218.

BENTHAM F. M.B. B.S. D.P.H. R.C.P.S. Medical Officer of Health for Kettering.

EASTWOOD C. G. B.Sc. M.R.C.S. L.R.C.P. D.P.H. Medical Officer of Health for Cambridge.

JONES D. J. B.Sc. M.B. Ch.B. D.P.H. Medical Officer of Health for Rugby and medical officer and divisional school medical officer.

PATERSON M. B. M.B. Ch.B. Temporary Assistant Medical Officer of Health for Lanarkshire.

WALES W. T. H. M.R.C.S. L.R.C.P. D.P.M. Deputy Medical Superintendent of Monmouthshire Mental Hospital.

WILDMAN J. H. M.R.C.S. L.R.C.P. D.P.H. Medical Officer of Health East Herts Combined Sanitary District.

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTHS

Brownridge—On Aug. 23 1948 to Phyllis wife of Dr. C. E. Brownridge of Farnham Almondsbury near Bristol a son.

Burgess—On Sept. 11 1948 at Ballard Lodge Alverstoke Hants to Phyl (née Hewitt) wife of Surgeon Commander P. G. Burgess R.N. a son.

Cutts—On Sept. 1 1948 in London to Ailsa wife of Dr. J. G. Cutts a daughter.

Davis—On Sept. 11 1948 at St. Helier Hospital Carshalton to Marjorie wife of Dr. H. Davis a daughter—Rosilyn Celia.

Deacon—On Sept. 2 1948 at the Birmingham Maternity Hospital to Sybil wife of Mr. A. L. Deacon F.R.C.S. Ed. M.R.C.O.G. a second son—Andrew Robert.

Middlemiss—On Sept. 5 1948 at Charing Cross Hospital to Maria (née van Sasse van Ysselt) wife of Capt. J. L. Middlemiss R.A.M.C. a daughter.

Rutter—On Sept. 2 1948 to Anne wife of Dr. W. Rutter of Netherfield House Seghill Northumberland a son.

## MARRIAGES

Brown—Hardy—On Aug. 27 1948 at Great Sampford Saffron Walden Essex Wilfred Stuart Brown M.R.C.S. of Shrodliss Hospital Watford to Betty Stella Hardy of Great Sampford.

Sears—Conn—On Sept. 4 1948 at University Chapel St. Andrews Dr. Harold Trevor Newton Sears M.B., M.R.C.P. Lond. of Tresladder Mullion Cornwall to Dr. Janet Sorley Conn M.B. Ch.B. (St. Andrews) of Kilnburn House East Newport Fife.

## DEATHS

Banks—On Sept. 9 1948 at Hadlow Down Sussex Alfred Banks F.R.C.S. aged 86.

Brooks—On Sept. 9 1948 at Manchester Royal Infirmary Peter Brooks M.B. Ch.B. aged 25.

Elder—On Sept. 7 1948 at 60 Rawlinson Road Southport George Tatham Davison Elder M.R.C.S. L.R.C.P. aged 73.

Kempster—On Sept. 7 1948 at 46 Portland Court Great Portland Street London W. Christopher Richard Kempster M.R.C.S. L.R.C.P.

M Vean—On Aug. 31 1948 as the result of a railway accident near Arbroath Ronald Henderson M Vean M.B. Ch.B. Captain R.A.M.C.

Pulling—On Sept. 9 1948 at 11 Old Steine Brighton Herbert Joho Pulling M.R.C.S. L.R.C.P. aged 88.

Soni—On Sept. 7 1948 suddenly at his residence 30 Wilmslow Road Withington Manchester Mul Raj Soni B.A. M.B. Ch.B. D.P.H. beloved husband of Edith Constance Soni.

Tuxford—Recently at Mayday Hospital Reginald Tuxford of Lower Addiscombe Road Croydon Surrey aged 75.

Wheaton—On Sept. 5 1948 Samuel Walton Wheaton M.D. F.R.C.P. of 16 Palace Road Streatham Hill London S.W. aged 86.

Willis—On Sept. 12 1948 at Barnes Convalescent Hospital Chesham Cheshire Euxenie Leeson Willis F.R.C.S. of 31 Wilmslow Road Withington Manchester second daughter of Captain F. R. Willis R.N. (Ret.) and Mrs. Willis of the Knapp Portesham Dorset aged 38.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug 28

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

Whooping cough* Deaths	3 162	248	60	48	8	1 618	193	75	59	6
Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	247	32	37	10	7	330	44	70	24	16
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	3 955	619	533	134	91	3 678	578	561	159	106
Live births Annual rate per 1 000 persons living	7 298	1234	903	398	236	8 377	1331	1001	392	259
Stillbirths Rate per 1 000 total births (including stillborn)	222	18	30	—	—	227	25	37	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales London (administrative county) will no longer be published

‡ Includes primary form for England and Wales London (administrative county), and Northern Ireland

§ The number of deaths from poliomyelitis and polio encephalitis for England and Wales London (administrative county) are combined

|| Includes puerperal fever for England and Wales and Eire

## EPIDEMIOLOGICAL NOTES

## Typhoid at Oswestry

The cause of the outbreak of typhoid fever at the Shropshire Orthopaedic Hospital at Oswestry has not yet been established. The investigators have been handicapped by the fact that so far it has not proved possible to type the infecting organism. One nurse who has had no symptoms has been shown to be excreting typhoid bacilli, but at the moment it does not seem likely that this was the original source of infection. There have been no cases in the nearby town or in the area surrounding the hospital. Up to Sept 13 there had been 33 cases isolated. 25 of these patients are members of the resident staff—the majority of them nurses or ward-marks, 5 are bed patients, and 3 are members of the non-resident staff of the hospital.

## Discussion of Table

In *England and Wales* there was a fall in the number of notifications of measles 837, whooping-cough 98, and dysentery 41, and the only rise of any size was 76 for scarlet fever.

Variations in the local trends of scarlet fever were quite small and the increase in incidence was mainly in the northern section of the country. The largest decreases in the returns for measles were Yorkshire West Riding 133, Gloucestershire 95, Northumberland 92, Bedfordshire 79, and Essex 64. The notifications of whooping cough in London were 67 fewer than in the preceding week, but in all other areas little change was reported. The returns of diphtheria showed no variation of any size from the preceding week.

The decrease in the incidence of dysentery was mainly contributed by Lancashire, where the notifications declined from 40 to 9. The largest returns of dysentery during the week were Yorkshire West Riding 15 (Sheffield C B 12), and Surrey 10 (Coulson and Purley U D 8). The increase in the notifications of acute poliomyelitis recorded last week was maintained. The largest centres of infection were Lancashire 7 London 6 Essex 6, Surrey 4, and Middlesex 4.

In *Scotland* increases were reported in the notifications of scarlet fever 57, whooping-cough 36 and diphtheria 11. Most of the increased incidence of diphtheria was contributed by Glasgow, where over one-third of the total cases were notified. A rise in the incidence of scarlet fever was reported from most areas of the country.

In *Eire* infectious diseases were less prevalent during the week, and the falls included whooping-cough 66 measles 28 and scarlet fever 22. The notifications of diarrhoea and enteritis were 5 fewer for the whole country, but an increase of 5 was reported in Dublin C B.

In *Northern Ireland* falls were recorded in the notifications of measles 10, whooping-cough 9, and scarlet fever 5. The first two diseases reflect the trend in Belfast C B, but the incidence of scarlet fever increased by 5 in this city during the week.

## Quarterly Return for Scotland

The birth rate during the second quarter was 20.7, which was 0.5 above the average of the five preceding June quarters. The infant mortality was 43 per 1,000 registered live births and was 11 below the five years average. Maternal mortality was 2.0 per 1,000 live births, being 0.1 above the rate for the first quarter of 1947 but 0.9 below the five years average. The general death rate was 11.4 per 1,000 and was 0.8 below the rate for the second quarter of 1947 and 0.6 below the average of the five preceding June quarters. Deaths from the principal epidemic diseases included 25 from measles, 19 from influenza, 14 from whooping cough and 10 from cerebrospinal fever. The death rate for all forms of tuberculosis was 84 per 100,000 and for respiratory tuberculosis 71. The former rate is 2 below that for the second quarter of 1947, but the latter is 3 above.

## Week Ending September 4

The notifications of infectious diseases in England and Wales during the week included scarlet fever 734 whooping-cough 2,996, diphtheria 105 measles 2,962, acute pneumonia 246 cerebrospinal fever 29, acute poliomyelitis 70, dysentery 64 paratyphoid 11, and typhoid 9.

The annual report for 1947 of the Medical Research Council of Ireland gives some account of the work of a number of special committees, notably those concerned with chemotherapy, goitre, and BCG. The Council's grant for general research has been increased from £5,000 to £10,000 a year and there is also a special grant of £6,000 for investigation into the chemotherapy of tuberculosis. It is expected that the scheme for BCG vaccination recommended to the Minister for Health will be put into operation this year.

## Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

### Infestation by "Harvesters"

**Q**—Is there any effective protection against infestation by harvesters which makes life in the country in the late summer quite miserable for many people? The insects, which I presume are in the larval stage seem to be harboured by rough grasses they burrow under the skin particularly in the axillae upper arms and other parts where the skin is soft and set up intense irritation. The very fine thread-like larva can be removed with a needle. All the usual insect repellents have been tried but none of them seems to be effective.

**A**—Attacks of harvest mites (*Trombicula autumnalis*) certainly cause great discomfort to sensitive people, who probably constitute the great majority. The larvae of these mites are parasitic on wild rodents and birds and sometimes attack other animals or man. They crawl up the limbs and usually halt where a tight constriction of the clothing obstructs their further progress, here they embed their mouthparts and feed. After a few days they drop off the host to the soil and pass the remainder of their lives in a harmless free-living state. The repellent dimethyl phthalate should be effective against this pest. An ointment containing about 40% of dimethyl phthalate should be rubbed over exposed limbs, this should prevent attacks for several hours or perhaps a day. Alternatively, undiluted dimethyl phthalate can be smeared over the socks or stockings, and perhaps also the cuffs, collars, and other openings of the clothing. The liquid should not be applied to artificial silk.

### Delivery after Operation for Prolapse

**Q**—A woman now in the sixth month of her third pregnancy had an operation for prolapsus uteri and lacerated cervix one year after the birth of her second child four years ago. The cervix is normal in size and position but there is a fibrosed scar along the anterior surface. Should she be delivered in her own home?

**A**—Several considerations are involved here, and much depends on what operation was performed on the cervix. If it was amputated, and particularly if the amputation was high, premature labour is likely to occur. Difficulty in dilatation of the cervix is a rare but nevertheless real possibility, irrespective of the height of the amputation. Other operations on the cervix are less likely to interfere with uterine function, although any scar which extends deeply may cause premature labour. Another important aspect of this case is the need to take all possible steps to minimize the chances of a recurrence of prolapse. These include a liberal episiotomy (even though it appears unnecessary) followed by its accurate repair and the avoidance of delay in the second stage of labour. Difficulties to be anticipated are the care of a premature baby (possible), cervical dystocia (rare) and repair of an extensive episiotomy incision (inevitable). The disposal of the patient depends on where these difficulties can be most efficiently overcome, and this in turn depends on the conditions of the patient's home, the availability of assistance, and the standard of the hospital facilities in the neighbourhood. Assuming the latter are good, then as a general rule it would not be in the best interests of the mother or child for the confinement to take place at home.

### Undulant Fever

**Q**—What is the latest treatment for undulant fever contracted in England? The patient is an elderly doctor who periodically suffers great discomfort and pain with the raised temperature.

**A**—No really long and well-controlled series of cases of brucellosis has been investigated. The following drugs have been known to bring about the termination of symptoms: (1) Neocarphenamine two or three injections intravenously

at weekly intervals (2) Sulphonamides, especially sulphadiazine 6 g a day for three weeks occasionally brings about cure (3) Sulphadiazine and streptomycin combined streptomycin, 2 to 4 g daily for 7 to 25 days, sulphadiazine, 4 g initially followed by 1 g four-hourly for three weeks (Spink, Hall, Shafer, and Brande, *J Amer med Ass* 1948, 136, 382) (4) "Antypol" (suramin) 1 g intravenously once a week (contraindicated if the kidneys are not healthy).

### Prevention of Ringworm of the Scalp

**Q**—A number of cases of ringworm of the scalp are occurring in the district and as M.O.H. I wish to circularize the local barbers and advise them what to do should they accidentally clip a sufferer's head. Is there any reliable information on percentage strength of and minimum immersion periods in commonly available disinfectants which will effectively destroy the ringworm fungus on barbers' instruments?

**A**—In an article by Schwartz and others (*J Amer med Ass* 1946, 132, 58) it is suggested that clippers could be sterilized without damage by working them for 10 seconds while immersed in petroleum oil (boiling-point 150 to 200° C) at 100° C, by boiling them for three minutes in a 2% saponated solution of cresol, or by immersing them in a 10% solution of this in the cold for 15 minutes. These methods of control led to a drop in incidence of ringworm of the scalp.

### Difficult Delivery

**Q**—What is the obstetric condition in which the baby is presenting by the vertex, occipito-anterior, and there is no evident disproportion but the mother fails to deliver herself? On application of the forceps with more force than is conducive to one's peace of mind the baby emerges with the marks of the blades under the angle of the jaw on one side and over the parietal bone on the other suggesting that the baby's head is inclined over towards one of its own shoulders rather than presenting squarely. I have delivered dozens in this condition and would rather deal with a straightforward occipito-posterior position which if diagnosed before the head becomes moulded to the wrong shape is manually rotated and delivered with comparative ease. I have asked several eminent obstetricians about this condition which I cannot find mentioned in any textbook and they talk learnedly but vaguely about the head not being "properly flexed" but they make no suggestions about causation or what should be done.

**A**—The suggestion that in these cases the foetal head is laterally flexed on the trunk, with the occiput fully rotated anteriorly, is difficult to accept. This state of affairs is not likely to occur except when the foetal neck is deformed, and experiments carried out on a doll and pelvis indicate that if it were as described merely locking the forceps would suffice to correct it. The probable explanation of the observations recorded is the pelvic application of forceps when the foetal head is incompletely rotated—i.e., when it is still lying with the sagittal suture in one or other oblique diameter. This is a common experience and results in forceps marks on the foetal head roughly in the sites described in the question. The treatment of this condition depends on accurate diagnosis of the position of the foetal head followed by a cephalic rather than a pelvic application of forceps, with or without preliminary manual rotation of the occiput to the front.

### Pteroyldiglutamic Acid in Malignant Disease

**Q**—Are pteroyldiglutamic acid and pteroyltriglutamic acid of value in malignant disease? Has any work similar to that of Leuchtenberger and Farber been done in the United Kingdom and is any hospital now working along these lines?

**A**—While earlier reports conveyed some indication of ameliorative effects from the treatment of malignant disease with pteroyldiglutamic acid and pteroyltriglutamic acid, such effects do not seem to have been confirmed in later clinical work whether in this country or in the United States. Demonstrable even if slight activity of this kind would still be of interest for the problem of tumour chemotherapy from the experimental aspect, but it seems clear that any such activity which these compounds possess is far short of rendering them of value in clinical practice.

### Venereal Disease

**Q**—What has been the peak rate of syphilis and gonorrhoea in the B A O R since the end of the war? Is the increase in the incidence in venereal disease shown in the Ministry of Health Report for the year 1946 likely to be a peak figure or has there been a further rise in 1947? Can any explanation be offered for the fact that this expected post-war rise in venereal disease is delayed as compared with the corresponding rise after the 1914–18 war? Is it true that the spirochaete can be transmitted in the seminal fluid for three to five years after a supposed "cure"? How long after the cure of syphilis is marriage permissible?

**A**—Figures for syphilis and gonorrhoea rates in the B A O R up to date are not available, but probably the highest were reached in 1946, when for one quarter they were in the neighbourhood of an equivalent annual ratio of 80 to 90 per 1,000. The civilian rates in this country for fresh infections with syphilis and gonorrhoea during 1947 fell well below those for 1946. If it is admitted that the expected post-war rise in VD was delayed longer after the 1939–45 war than after the 1914–18 war, and it is not so clear that it was, there are many possible explanations, none of which is very convincing. Spirochaetes have been demonstrated in the seminal fluid of latent syphilitics some years after the date of infection, such persons would presumably be able to transmit their infection. It is usually considered safe to allow a syphilitic person to marry when five years have elapsed from the time of infection, but in the case of a syphilitic woman it is wise to recommend antisyphilitic treatment during any pregnancy in order to ensure the birth of a non-syphilitic child.

### Treatment of Diverticulitis

**Q**—How should one treat loss of weight and increasing constipation in a case of diverticulitis of the lower colon? A man aged 57 had been diagnosed by a competent radiologist as suffering from diverticulitis. He still plays golf and tennis. Most of his teeth have been extracted and it is only within the last year that he has suffered from increasing constipation. He now complains of flatulence and abdominal discomfort after defaecation—his bowels never seem to be properly emptied. He has lost over 1 st (6.35 kg) and his weight is now 10 st 5 lb (65.77 kg). Myalgia and weakness are present in both groups of extensor muscles of the thighs. He eats anything except food containing roughage and takes emuls paraffin, c phenolthol, two dessertspoonfuls every night. Is there any other treatment and what is the prognosis?

**A**—The general symptoms of which this patient complains are severe for simple diverticulosis even when accompanied by diverticulitis obviously the possibility of carcinoma must be considered. The description suggests that the lesion would be within view of the sigmoidoscope. Provided malignant disease has been excluded the indications are to maintain regular evacuations with liquid paraffin and a low residue diet. It sounds as though these measures were now losing their efficacy and that recurrent episodes of partial obstruction were taking place, hinting at a progressive stenosis of the bowel's lumen. If this is so, surgical treatment will become necessary, and it would be advisable to consult a surgeon before complete obstruction supervenes and the patient's health deteriorates further.

### Dangers of Cinchophen

**Q**—I have been warned of the danger of using cinchophen for the removal of excess uric acid in the blood. Can you suggest any safer alternative? What are the principal dangers of cinchophen?

**A**—Cinchophen is the only efficient substance to increase the excretion of uric acid. Its principal danger is that it may cause hepatitis, and this has been known to go so far as to cause jaundice and death. This is, however, a very rare occurrence. In 1931 White estimated the annual consumption of cinchophen in the United States to be 90,000 lb (40,823 kg), so that the proportion of cases in which liver damage occurs must be very low. Cinchophen irritates the stomach, therefore while it is being used sodium bicarbonate should also be given (though not simultaneously), on the first day 15 g (225 gr) of sodium bicarbonate and 5–10 g on the following days. This also keeps the urine alkaline. Plenty of fluid should be taken.

Other points about the toxicity of cinchophen were discussed in a question and answer published on Aug 28 (p 450).

### Hypoplastic Anaemia

**Q**—Are x-ray therapy, electrotherapy, sulphonamides or residence or a visit to the Tropics contraindicated in cases of hypoplastic anaemia?

**A**—In cases of hypoplastic anaemia there is no contraindication to electrotherapy. Residence in the Tropics is contraindicated only in so far as it carries some additional risk of disease—e.g., amoebic dysentery—which a person with hypoplastic anaemia could less well support. X-ray therapy is contraindicated, although evidently there are circumstances in which it would be better to have x rays and risk the possible ill effects on the bone-marrow rather than go without them and suffer still worse effects. Much the same considerations apply to the use of sulphonamides, certainly one would not use them unless the patient had an infective condition which had failed to respond to penicillin and other measures.

## NOTES AND COMMENTS

**When was Hughlings Jackson Born?**—Dr E H DERRICK (The Queensland Institute of Medical Research, Brisbane) writes: Although authorities agree that Hughlings Jackson was born at Green Hammerton, in Yorkshire, they disagree as to whether this auspicious event occurred in 1834 or 1835. Supporters of 1834 are Power and Thompson's *Chronologia Medica*, Garrison's *History of Medicine* and Dorland's and Gould's Medical Dictionaries. On the other hand the obituary in the *British Medical Journal* (1911, 2, 950) and Bailey and Bishop's *Notable Names* give 1835. The Section of Neurology of the Royal Society of Medicine celebrated the centenary on April 4, 1935 (*Journal* 1935, 1, 769). This disagreement about such an illustrious figure is surprising. Can it be authoritatively settled?

**Air Conditioning**—Lieutenant-Colonel H G G ROBERTSON writes from Hamburg. In "Any Questions?" (Aug 14, p 363) a correspondent asks about air conditioning. Perhaps the following brief outline of the principles of air conditioning may be helpful. By means of a pump air is drawn from outside through a filter which rids it of gross particles. It is then passed through a screen of sprayed water at a temperature well below that which is finally required of the air. This washes it, cools it, and raises its humidity to saturation point. The air is then heated to the desired temperature, and, as hot air is capable of absorbing more water vapour than cold air, and the actual amount of water remains the same, the relative humidity falls. By suitably adjusting the temperature of the cooling water it is possible to obtain almost any desired temperature and relative humidity in the air that enters the room. It is, of course, essential that doors and windows be kept closed to prevent the entry of the outside air.

### Corrections

In amplification of its statement on the "Streptomycin Treatment of Tuberculosis" the Ministry of Health adds that streptomycin will nevertheless still be available for the treatment in any hospital of cases of acute military meningitis, and ulcerative tracheo-bronchitis and laryngeal tuberculosis, but in special instances applications for it should now be made to one of the Regional Distribution Centres instead of, as formerly, to the Ministry of Health.

Messrs Henry Kimpton inform us that they are the English agents for *Clinical Laboratory Methods and Diagnosis* by R B H Gradwohl, noted in "Books Received" (Sept 4, p 478), and that the price is 10 guineas.

We regret that owing to a printing error the name of Mr John Gilroy, who painted the presentation portrait of Sir John Herbert Parsons (Sept 11, p 529), was mis-spelt.

Dr M H Logg (Medical Superintendent, Grove Park Hospital, London, SE 12) writes: Referring to the announcement regarding the distribution of streptomycin in your issue of Sept 11 (p 527), I would call your attention to the fact that the telephone number of Grove Park Hospital is Lee Green 1077—and not as printed Lee Green 1547 (which happened to be the earlier telephone number until 1946).

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 18 1948

## FREE HOSPITAL PLAN IN THE TRANSVAAL OPPOSITION BY THE MEDICAL PROFESSION

The Provincial Council of the Transvaal—in the Union of South Africa it is the Provincial and not the Union Government which undertakes such legislation—has enacted an Ordinance known as the Public Hospitals Ordinance (Transvaal) 1946 coming into operation in the present year, which provides free hospital treatment for all members of the community. The free treatment extends to out-patients and to patients attending detached clinics, as well as those in hospital beds. Such public patients, their hospital charges being met, will be given free choice of having also the medical services which the hospitals will again provide without payment or, alternatively, of selecting their own medical attendants and paying them. There is no means test.

Hitherto about 70% of European patients and practically all non-European patients have received free hospital service, including medical treatment. The remaining 30% of Europeans have paid their hospital charges and doctors' fees. Henceforth the service will be free for all in the sense in which any service is free which is paid for out of taxation.

At the same time it is admitted that there is a shortage of hospital beds and nurses, so that all patients cannot be accommodated. The Ordinance provides that the determining factor in allocation shall be the urgency of the medical need of the patient—in other words, medical necessity, not financial hardship, shall be the criterion for free treatment. The medical profession in the Transvaal, on the other hand, while in favour of a comprehensive health service, is protesting against the Ordinance on the ground that a means test ought to be imposed. The means test suggested is that single persons with an income over £500 and married couples with an income over £1,000 should not be eligible for free hospitalization. The issue really concerns those 30% of Europeans who have hitherto paid for their hospital accommodation and also for their medical services while in hospital. During the two years that the Ordinance has been in the offing there have been negotiations between the representatives of the medical profession and the Provincial department, and a good deal has been achieved, but this one bone of contention—the means test—remains.

Opposition to the Ordinance has been voiced by the three Transvaal Branches of the Medical Association of South Africa. In a plebiscite in which 79% of the profession voted there was a 91% overall majority against the Ordinance (1,016 against, 93 for), the majority was rather less (86%) among the practitioners of Johannesburg and Pretoria, and rather more (96%) among those in the rest of the country. The Federal Council of the Medical Association met in Pretoria at the end of July and passed a motion advising members and non-members of the Association not to accept appointments under the scheme nor to assist in any way in the implementation of the Ordinance while serving on hospital boards or committees or advisory councils unless the conditions of their present contracts made this unavoidable. They were also advised to continue to serve temporarily under the conditions of the earlier Ordinance of 1928 in order that poor persons in hospital should not be debarred from essential medical services. The motion rejecting the Ordinance was carried *nemine contra-*

*dicente* one member not voting. It was also resolved to approach the Union Minister of Health, asking him to intervene.

The Ordinance is supported apparently by the various political parties and labour organizations but the likelihood is that it will be worked by only a part of the medical profession, and that most general practitioners will be out of it. There is some talk in the latest advices received from South Africa of a further approach to the administrator of the Ordinance. One difficulty seems to be the outlying hospitals, where the medical service is sometimes indifferent, and it is the intention of the administration to tighten things up.

### The Medical Position

The position of the medical profession calls for careful statement. The profession has repeatedly expressed itself in favour of a comprehensive health service to include free medical care for all sections of the community. Apparently such a scheme is not yet practicable in the Transvaal, and meanwhile the profession is willing to assist in the rational development towards such a scheme. Until the whole profession can be absorbed into an organized health service, however, it is maintained that free services in hospital should be limited to the provision of accommodation, nursing, food, and ancillary services, and that free medical treatment should be confined to those who cannot afford to pay for it.

It is pointed out that with free medical treatment in hospitals, out-patient departments, and clinics there will be nothing left for the private medical practitioner except domiciliary services, on which many practitioners cannot make a living. Moreover, the virtual exclusion of the private practitioner from the public hospitals, owing to the availability for the patient of the free medical services of the hospital itself if he chooses to have them, will result in a lowering of the standard of professional skill and ability among private practitioners.

The profession accordingly proposes that as there is an acknowledged shortage of hospital accommodation the Ordinance should be amended to provide that, pending an improvement in this respect, where there is alternative accommodation in private institutions or where the conditions of patients permit of their being cared for adequately at home, preference in the allocation of the available hospital beds should be given to the poor.

As a means of dealing with persons of the middle-income group who are liable to be embarrassed by the expense of serious illness, it is suggested that they should insure themselves against such contingencies. It is stated that in the Transvaal already there are several hundred thousand persons enjoying the benefits of such insurance. For those not insured the Association has offered to work out a formula which would take into account the person's circumstances in relation to the costs of his medical care together with a tariff of medical fees beyond which it would not be permissible for a practitioner to charge a private patient in hospital. An offer to do this was actually made to the administration before the Ordinance was enacted, but it was rejected, and the Ordinance specifically precludes the administrator from prescribing fees or charges payable to private medical practitioners in respect of in-patients who may elect to be treated by them.

In a statement drawn up by the Action Committee of the Southern Transvaal Branch of the Medical Association of South

Africa it is pointed out that the Ordinance itself lays down that people will be received into the public hospitals only in so far as adequate accommodation is available. It therefore seems to suggest that there will not be accommodation for all who require it. It is argued on behalf of those who support the Ordinance that the administrator should take into consideration the home circumstances of patients in determining the urgency of their medical need for treatment. This seems to the committee to substitute a less definite criterion than the means test and one which does not really protect the poor patient.

"If the Province is really in earnest about providing free hospital services for all who need them, it should be prepared to subsidize all sick persons who are excluded from public hospitals by virtue of any existing shortage of beds, and who for this reason are compelled to go to private institutions. This would be equitable and would be supported wholeheartedly by the medical profession."

As it is, some people will undoubtedly still be forced to seek and pay for accommodation in private institutions while others who are equally or better able to afford the expense will be admitted free to public hospitals.

The local medical profession has proposals for amending the Ordinance which are in keeping with the principle of free hospitalization and which, it is claimed, would if accepted confer great benefits on the public by providing such accommodation, nursing, and ancillary services free for all, and ensure that the fees charged to those who could afford to pay for medical treatment would be regulated in a reasonable manner.

## N.H.S. SUPERANNUATION SCHEME

### OPTION TO RETAIN RIGHTS

*The Ministry of Health has issued the following leaflet (S D A) for the guidance of officers transferred to the National Health Service who may exercise an option to retain rights corresponding to those enjoyed under their previous superannuation schemes*

1 Many persons who are transferred to the National Health Service on July 5, 1948, will have been subject to one of the following schemes immediately before that date

- (a) the Superannuation Acts, 1834-1946 (Civil Service),
- (b) the Asylums Officers' Superannuation Act 1909,
- (c) the Local Government Superannuation Act 1937,
- (d) a local Act Superannuation Scheme, or
- (e) the Insurance Committee Officers' Superannuation Scheme

2 The National Health Service Superannuation Scheme (for all those who come into it) provides benefits which, taken as a whole, are at least equal actuarially to those enjoyed immediately prior to transfer. But the actual benefits are different in some cases—thus, compared with the local government scheme, there is a smaller pension but there are compensating advantages—a lump sum retiring allowance, a death benefit, a widow's pension, a minimum incapacity pension, and a short-service gratuity. Any transferred person with existing rights under the provisions referred to in paragraph 1 is free to continue, if he wishes, with rights corresponding to those he has now, at the same rate of contribution (if any), instead of coming on to the terms of the new Scheme. If a transferred employee wishes to exercise this option he must submit a notification within three months after the date of transfer (July 5 1948) that he does not wish to avail himself of the benefits of the new Scheme.

3 The purpose of this leaflet is to bring this to the notice of those who may be interested so that they can give notice of their choice by Oct 4 1948, if they do not wish to have the benefits and contribution rates of the Health Service Scheme. Before deciding on this it would be wise first to compare the benefits of the existing scheme with those of the new Health Service Scheme with the help of the explanatory booklet<sup>1</sup> which has been issued to all employees who are to be transferred on July 5, 1948. The new scheme has a greater range of benefits than any of the existing schemes to which this leaflet refers.

<sup>1</sup> Superannuation Scheme for those engaged in the National Health Service. An Explanation. H.M.S.O., London.

4 Thus, officers from the local government or Insurance Committee service may see considerable advantage in the cover provided by the death and short-service benefits, payable after only five years' service, in the widow's pension, in the minimum limit to the incapacity pension, and in the return of contributions in all cases with interest except where an officer leaves on grounds of fraud or misconduct. The same points apply to the officer in a mental hospital or in a mental deficiency institution, with the added one that all contributions (including past contributions) will be returnable on resignation. To make the new benefits actuarially equivalent to the old ones, the lump sum retiring allowance payable to an officer who decides to accept the Health Service Scheme (i.e., does not exercise the option of continuing subject to the conditions of his existing scheme) will be increased by  $\frac{1}{2}\%$  in respect of each year of past contributing service and  $\frac{1}{4}\%$  in respect of each year of past non-contributing service under the old scheme, if that scheme did not provide for a death gratuity; this recompenses him for the fact that he has not had a death cover over his earlier years of service as would have been the case if the Health Service Scheme had applied to him throughout his service. If the officer is married and the retiring allowance in the Health Service Scheme is reduced because of the widow's pension liability, the  $\frac{1}{2}\%$  and the  $\frac{1}{4}\%$  will be increased to  $1\frac{1}{2}\%$  and  $\frac{3}{4}\%$  respectively.

5 A special word must be said about officers in the mental health service. Under the Health Service Scheme provision is made whereby those who come within the category of "mental health officer" may qualify for a pension at 55. The term "mental health officer" means a member of the staff of a hospital or an institution for the treatment of defectives who devotes the whole or substantially the whole of his time to the treatment or care of mental patients or defectives. It is possible that certain persons who are ranked as officers or servants of the first class under the Asylums Officers' Superannuation Scheme may not come within the mental health officer category. Any such person who wishes to retain the benefits of early retirement under the Asylums Officers' Scheme must, to do so, exercise his option. That option if exercised, will cease to have effect if he becomes at any time employed otherwise than for the purpose of a hospital or part of a hospital used for the treatment of mental patients or an institution used for the treatment of defectives.

6 Each person must himself make the choice. The rates of contribution and the benefits of the National Health Service (Superannuation) Regulations, 1947 are set out in Sections B and C of the explanatory booklet. Examples I and III in Section K of the booklet are also of particular interest.

7 The regulations themselves can be purchased direct from H.M. Stationery Office or through a bookseller, price 1s 10d net (by post 2s).

8 Any person desiring to exercise the option which has been described can obtain the appropriate form of application from his employer on request. The form, to be effective, must be completed on or after July 5, 1948, and, as has already been stated, it must be submitted to the officer's National Health Service employing authority within the period July 5, 1948, to Oct 4, 1948.

9 Contributions at the appropriate rate under the new Scheme will be deducted from pay as from July 5 1948, until an option to continue on the terms of an existing scheme is received. When an option is exercised those contributions will be adjusted back to July 5, 1948.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar

*Non-County Borough Councils*—Dartford, Radcliffe (limited to future appointments), WallSEND

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Tyldesley

## National Health Service News

### Income Tax and Superannuation

We are informed by the Inland Revenue Department that, in cases where a practitioner opts out of the superannuation scheme the 8% contribution paid to the practitioner by the Government towards the maintenance of his insurance policies will be treated as income chargeable for income tax, and the position will not be affected by the use to which the practitioner puts the contributions.

The full premiums on the policies will thus continue to be paid by the practitioner out of his income as computed for income tax purposes, and the question of relief in respect of these premiums under Section 32 of the Income Tax Act, 1918, will not be affected by the fact that the Minister contributes towards the cost. Premiums on deferred annuity policies and endowment assurance policies will rank for relief subject to the present statutory restrictions.

In cases where the practitioner contributes to the superannuation scheme the 8% contribution of the Government is not received by the practitioner and will not be chargeable to income tax. The 6% contribution made by the practitioner will rank for income tax relief but the earned income relief to which he is entitled will be affected to the extent of the amount of this contribution. In other words, the earned income relief will be assessed on the income of the practitioner less the 6% deduction.

## Correspondence

### Tenacity and Leadership

SIR—With reference to Dr W A Bourne's letter (*Journal* Sept 4, p 499), there is one point which is so often repeated but which is so obviously wrong that I feel that it should be contradicted lest future generations should believe it to be true. I refer to the statement that 'a majority of practitioners opposed the health service in the second plebiscite'.

The facts are that nearly 9,600 general practitioners were not in favour of entering the service, whereas assuming there are 21,000 general practitioners, over 11,400 were in favour or did not vote. But the 9,600 were not in favour knowing that they would be released from any pledges unless their number reached a certain safe percentage. Only one thing, therefore, was certain from the plebiscite, and that is that over 5,700 general practitioners had decided to join this service and it is more than likely that those numbers would have been greatly swelled if the safeguard clause had been omitted.

I have always opposed the health service as it stands to day, for I feel that it can only lead to a gradual lowering of standards in general practice, but the lot of the G.P. is far far better than I dared hope it would be, and for this we have to thank the tenacity and leadership of our Association and Negotiating Committee—I am, etc.,

Newport Pagnell Bucks.

A A CLAY

### Obstetric Committees

SIR—Mr E Farquhar Murray (*Supplement* Sept 4, p 105) considers that something is radically wrong and impracticable in the present attempt to improve the midwifery service by dividing doctors into those who are on the special list and those who are not. He also deprecates the publishing of the names of 'special list' doctors only, in post offices. He goes on to say that the teaching and practical experience given students are sufficient to give them a reasonable working knowledge and yet he shall I say objects to the public having available such information as will enable them to differentiate between a doctor who has a reasonable knowledge and one who has attained efficiency in all aspects of the confinement by post-graduate study or by working as an assistant to a special list doctor.

Mr Farquhar Murray illustrates the grief of the newly qualified and keen doctor who finds he has not been appointed to the special list. Does he refer to the young doctor who is

keen to make money quickly or is keen to become an efficient doctor? If the former I feel that the obstetric committee will in the long run be his best friend, if the latter he will be more interested in acquiring further experience before entering general practice on his own. Most of the letter referred to has been in the nature of destructive criticism of obstetric committees throughout the country, who are conscientiously trying to improve the standards of domiciliary midwifery but the unfortunate reference is apparent when the author states that the vast majority of midwives calls are for such minor things as lacerations. Lacerations of the perineum are probably the commonest accidents in obstetrics, and, although not in themselves serious, their consequences, if neglected or carried out by the young doctor who has performed few if any repairs before qualifying, may be far-reaching in predisposing to uterine displacements, associated chronic ill health, and reduced efficiency. I will readily admit that answering nurse's call gives the young doctor confidence and experience, but I consider that the young doctor, and the young mother, would be more confident if a 'special list' more experienced doctor was at hand to supervise the case.

I sincerely trust that, with regard to future applications obstetric committees throughout the country will not include a doctor on the obstetric list for the area until he satisfies them that he is capable either by experience or special qualifications of taking full charge of domiciliary midwifery, and that they request their executive council to bear this in mind especially when considering applications from doctors for vacancies in single-practice areas—I am, etc.,

Malton Yorks

C OGILVIE MARR

SIR—I must thank Professor Farquhar Murray (*Supplement* Sept 4, p 105) for his very dispassionate arraignment of what I have come to refer to as the affair of the obstetric sheep and goats. Not only is there something radically wrong here but there appears also to be something potentially very dangerous. The dangers arise especially from two angles. The first is that these committees might be used to enforce uniformity in treatment either as a result of directions from above or misguided enthusiasm on the part of individual members—in other words, clinical interference. The second danger is that this method of approach might be employed in other spheres of medical practice. We might have pneumonia committees, measles committees, and heaven knows what else. The truth seems to be that in the past we all with our varying interests and capabilities have tended to do the work which our consciences told us we were capable of and to pass on or avoid the rest, and, if we have not, our patients have soon found us out. This on the whole has worked reasonably well and at any rate has worked better than the type of planning foreshadowed by the obstetric committees is ever likely to do—I am, etc.,

Wolverhampton

R S V MARSHALL

### Mileage Fund

SIR—In a note appended to the letter from Dr A Kellie Brooke (*Supplement* Aug 14, p 84) the Secretary of the Association writes, "To double the number of persons in respect of whom mileage is paid is not to double the number of miles travelled. Accordingly a doubling of the mileage fund means an increase in the payment per mile travelled."

No one will contest the fact that previously the mileage grant has only been a part payment for travelling expenses in a country practice. The remainder (estimated by Dr A Kellie Brooke as 2½ times the number of panel patients on whom the practitioner claims mileage) were the private patients of the doctor, and from them he made a special claim for mileage in the assessing of his fees. In this way as in all private practice the private patient was in fact subsidizing the panel patient. Now, when the private patient has been to all intents and purposes abolished, the country practitioner has a right to expect a substantial increase in the mileage rate per mile of those on his list.

But there is more in it than merely the matter of miles travelled. It is obvious that where patients are situated near the surgery of a doctor or on convenient bus routes they will be able far more easily to attend at the surgery for minor treatment than when they are at a distance and a long way from a bus route. The number of domiciliary visits in the country is therefore necessarily increased in comparison with an urban

practice, and the time taken in making these visits is very much longer. All this should be taken into consideration in the assessing of the mileage grant. We feel most strongly that to make the mileage grant a call on the capitation rate is unfair. This should be a separate and independent fund as it was under the NHI.

The Secretary also states in the same note that after the inducement fund has been divided between England, Wales, and Scotland "applications will be invited for special inducement grants for consideration by the medical practices committees." As we read this, the inducement fund is not to be used to attract practitioners to unpleasant places or into arduous practices but is to be a fund held by the medical practices committee, who are to be induced into parting with it by those general practitioners who may consider themselves sufficiently unhappy in their practices to justify their making an application. The man who puts up the best case will get the greatest grant. How unfair! How like begging for charity it all is! Surely criteria can be laid down which will enable executive councils in co-operation with the local medical committees to distribute the fund as originally intended—We are, etc.,

R M S MCCONAGHEY  
A J EDGCOMBE ROWE

Dartmouth

SIR—The answer of the Secretary of the Association to the letter from Dr A Kellie Brooke (*Supplement* Aug 14 p 84) indicates one assumption as regards rural mileage which is surely not justified by the actual facts. The payments from the mileage fund before July 5 1948, did not represent an adequate return for the time spent in visiting the insured patients nor for the car expenses, but that did not matter very greatly, as this loss was subsidized by adding to the fees charged for private patients. As this no longer applies and the suggested total mileage fund is no more than an increase proportionate to the increased number of State patients an adequate remuneration will still not be provided for the rural doctor for the time taken and for his increased car expenses.

This mileage question raises one very important matter which so far as I can remember has not been ventilated in any of the columns of the *Journal*. It is surely quite unreasonable to expect any rural patient to walk 4, 5, or 8 miles to a doctor's surgery and back again even if the lesion is only a finger ache, as otherwise the rural patient is unfairly penalized. Could we have some authoritative statement on this point and also on the question of the delivery of rural medicines?—I am, etc.,

Moretonhampstead Devon

W D GLYNN JONES

### Free Drugs for Private Patients

SIR—May I join Dr Humphrey Foxell (*Supplement* Aug 21, p 90) and many others in asking that the BMA should insist that the Minister be compelled to stand by his printed word and that private patients should be given their rights in being allowed drugs under the NHS? It is obvious that the Minister is using the cost of drugs, deliberately inflated by a purchase tax, as a lever to force patients into the Service in the same way as the compensation for goodwill was the lever that so surely forced many unwilling practitioners into the net. Surely there is some effective action we can take to ensure that our private patients get a square deal. They will never get fair treatment from the Minister unless his hand is forced—I am, etc.,

Bournemouth

ROBERT RISK

### Obstetrical Service

SIR,—It is deplorable that the much-vaunted obstetrical service of the NHS should oblige practitioners to perform only two antenatal examinations on each pregnant woman. Discussing this question recently with a Ministry official I was told, in effect, that the Service depended on the professional integrity of the practitioner to perform the right and proper number of such examinations but that the minimum of two was stated because of the low composite fee. Why not give the British mothers the promised service with routine antenatal examinations at the recognized intervals and paid for at the rate of half a guinea? Then we would at least feel that there was less of an imposition on our professional sense of responsibility—I am, etc.,

Leaford, Lincs.

ROLAND CUBITT

### Charges for Hospital Beds

SIR—I think it was possible before the war to find accommodation in private nursing-homes around six guineas a week, the really lavish ones naturally charging more. There have lately been many complaints from patients and doctors regarding the excessive charges made for private rooms under the control of regional boards. I feel that this matter may be taken as a test of sincerity. If the Minister really intends to play fairly with private doctors and private patients he will make certain that those paying for private accommodation are not, as might now appear, subsidizing public patients. Not long ago one of your correspondents rightly pointed out that it was his own business if he cared to go without drinks and smokes to make his sick relative more comfortable. In my opinion this is one of the numerous issues which the BMA should now fight, and win. In no case should private accommodation be charged above cost, and there seems much to show that many charges are now cruelly exorbitant—I am, etc.,

Hadley Wood Herts

G C PETHER

### Too Many or Too Few?

SIR—Could you please tell me whether there are too many doctors or too few? I ask this somewhat naïve question simply because I am genuinely bewildered about the matter. On the one hand we have the sponsors of the National Health Service warning the public not to expect the full benefits of the scheme just yet owing to the grave shortage of doctors, nurses, health centres, etc., while on the other hand it is pretty obvious to those of us who are not hypocrites that newly established practitioners who joined the Service after the general rush to "sign on" with doctors are likely to be in for a lean time. I know that this view is shared by at least one important official employed by the London Executive Council, and I myself know of several such newly established practitioners who are still sitting in their newly painted surgeries with very little to do, very few patients on their list, and very little money to support their families on—I am, etc.,

London SW 3

VICTOR CONSTAD

### Guidance from the Past

SIR—The following extract from the Presidential Address delivered at the Norwich meeting of the British Medical Association in 1874 by my great-uncle, Dr Edward Copeman, FRCP, seems to have some interest in connexion with recent events.

He said "So Gentlemen I believe it will be in the future, only establish principles which are just and of undoubted benefit to the profession, and the powerful agency of this great society, more and more powerful as the years roll on, will most assuredly at last secure the favourable consideration of the Government and force upon it the necessity of granting such reasonable demands as we may unitedly urge upon it. At any rate I feel perfectly assured that no act of the legislature which we as a body feel to be detrimental to the profession, or to the community, will have a chance of passing into law in the face of such influence as that now beginning to be possessed by the British Medical Association."—I am, etc.,

London W 1

W S C COPEMAN

### Ophthalmic Certificates

SIR,—While agreeing with your correspondents, Drs B Sandler and T R Thomson (*Supplement*, Aug 14 p 87), that the ophthalmic certificate is yet another imposition on the general practitioner, I would point out that in the wider sphere it has its uses. One of the Minister of Health's slogans is "Harley Street for All," and by starting a service which offers consultation with an ophthalmic medical practitioner or an ophthalmic optician and of which initial advantage can only be taken after obtaining a medical certificate, he surely produces a bias (even if "you are not bound to take my advice") towards the ophthalmic medical examination.

This must be in accordance with medical policy, and by the conscientious issue of certificates—which are only necessary once in the lifetime of each patient—the general practitioner is helping his specialist colleague towards the ideal of medical eye examination for all—I am, etc.,

**Doubt about Capitation Fee**

SIR—It is impossible to ignore the note of anxiety for our financial futures running through the letters from members which you publish week by week in the *BMJ*. With less than a month before our first payment is due under NHS none of us appears to know what capitation fee we are to receive. All we know is that it will be "somewhere between 15s and 18s. Doctors, like other members of the community, have bills to settle, and they cannot be settled without money. A number of us are going to suffer considerable financial loss under the health service at a time when everybody else is either getting an increase in wages or asking for one. The financial side of the health service, as far as it affects the doctors who are to run it, is receiving far too little attention. Is the B.M.A. doing anything about it?—I am, etc.,

Brookmans Park, Herts

JAS J DWYER

**H.M. Forces Appointments****ROYAL NAVY**

Surgeon Captain F L H MacDowel has been placed on the Retired List.  
Acting Surgeon Lieutenant-Commander A C Hamer to be Surgeon Lieutenant-Commander

**ROYAL NAVAL VOLUNTEER RESERVE**

Surgeon Lieutenant J D Stride to be Surgeon Lieutenant-Commander

Temporary Surgeon Lieutenant M D Kipling has been transferred to List I of the Permanent R.N.V.R., in the rank of Surgeon Lieutenant

Temporary Surgeon Lieutenants E G Shaw and P W E Sheldon have been transferred to List II of the Permanent R.N.V.R., in the rank of Surgeon Lieutenant

Temporary Acting Surgeon Lieutenant O C A Scott to be Temporary Surgeon Lieutenant

**ARMY**

Colonel H G Winter, M.C., late R.A.M.C., has retired on account of disability and has been granted the honorary rank of Brigadier.  
Colonel E C Lang D.S.O., late R.A.M.C., has retired on retired pay.

Colonel G H Haines, M.C., late R.A.M.C., having attained the age for retirement, is retained on the Active List supernumerary to establishment.

**ROYAL ARMY MEDICAL CORPS**

Lieutenant-Colonel G W Crimmin O.B.E., has retired, receiving a gratuity, and has been granted the honorary rank of Colonel.  
Lieutenant Colonel H H Atkinson has retired.

Major E H P Lassen D.S.O. to be Lieutenant-Colonel

*Short Service Commissions*—Captain A C Pinkerton, from Emergency Commission to be Captain. D J Cowan to be Lieutenant. Captain H M S G Beadnell has retired receiving a gratuity and has been granted the honorary rank of Major. The notification regarding Lieutenant A D Roy in a *Supplement* to the *London Gazette* dated May 11, has been cancelled.

**TERRITORIAL ARMY****ROYAL ARMY MEDICAL CORPS**

Lieutenant-Colonel J G Morgan, C.B.E., T.D., has been granted the acting rank of Colonel.

Captains F C Mayo, K C Mackelvie and R De Soldenhoff to be Majors

Lieutenant S F Seelig to be Captain and has been granted the acting rank of Major

Lieutenants W Duncan, M A O'Sullivan, R T G Craig and E Pringle to be Captains

R P R Allan to be Lieutenant

**TERRITORIAL ARMY RESERVE OF OFFICERS ROYAL ARMY MEDICAL CORPS**

Captain W J E Phillips, from Active List to be Captain, and has been granted the honorary rank of Major

Captain G H A Robinson from Active List to be Captain

**REGULAR ARMY EMERGENCY COMMISSIONS****ROYAL ARMY MEDICAL CORPS**

Lieutenant-Colonel P Drummond has relinquished his commission and has been granted the honorary rank of Lieutenant Colonel

Lieutenant (Acting Lieutenant-Colonel) C D Bruce has relinquished his commission and has been restored to the rank of Lieutenant-Colonel, late R.A.M.C., T.A.

Major C H Bentley has relinquished his commission and has been granted the honorary rank of Major

War Substantive Major W S Charlton has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel

War Substantive Captains D R Cairns, W Fabisch, T L Tan, R J Stout, N H Rutledge, and E A Fiddian have relinquished their commissions and have been granted the honorary rank of Major

War Substantive Captain H R McNair has relinquished his commission on account of disability and has been granted the honorary rank of Major

*Short Service Commission Specialist*—War Substantive Major P Forgacs has relinquished his commission and has been granted the honorary rank of Lieutenant-Colonel. Captain W O Spence has relinquished his commission

Captains J M Stowers and M A Cooke have relinquished their commissions on account of disability and have been granted the honorary rank of Captain

Captain J Flintner has relinquished his commission and has been granted the honorary rank of Captain

War Substantive Captains V P Poonosamy, L Allen, J C McNeilly, and T E Marshall have relinquished their commissions and have been granted the honorary rank of Captain

War Substantive Captains O D Cuthbert, H E De Wardener, J S Marshall and A B Wood have relinquished their commissions on account of disability and have been granted the honorary rank of Captain

War Substantive Captain R M Saleh has relinquished his commission

Lieutenant (War Substantive Captain) T E Harvey has relinquished his commission and has been granted the honorary rank of Captain

Lieutenants P L H Davey and S Eden have relinquished their commissions on account of disability and have been granted the honorary rank of Lieutenant

J Lintner to be Captain

Lieutenants W C MacPherson, R J Mitchell, R Armatage, J C Batten, D G Breeze, N H Birch, W J H Butterfield, A Blench, J Butler, D F Barrowcliffe, G M Colson, H Caplan, J Cox, P E A De Caestecker, J J Duffy, G Fyfe, H B Farrell, R H Freeman, D W S Gordon, R J Howat, G Hughes, C W L Jones, J G Kendall, J R Leslie, J D Lumsden, G H Luffingham, H S Levy, J Moss, D McI Maxwell, S Moller, M C McLeod, W H Oldenshaw, B W Orchard, C MacL Ogilvie, J P Pracy, G S Plaut, A G Pollen, F W Richards, F L Rawson, J C Rogers, C G Sim, G W Storey, T B Surling, R J H Smith, M K Towers, N Weiner, P Wise, J T H Wise, F E Webb, P R J Williams, L Walkden, G T Watts, J R May, B P Hill, M L Sacks, S C Harper, G Adam, S Cope, A M Davies, J Dillon, P J D Heaf, R E Jenkins, R H N Lake, P A R Lorne, A C Milne, J L Middlemiss, H M Park, D A Petrie, J H Raphael, J A Reynolds, R E N Tattersall, F W Thomas, R W Lawrie, S G M Mackay, A C Allin, H I O Armstrong, P J Burdon, J M Dunbar, K G Gadd, H Howell-Jones, A Holmes, N Harrison, D W K Kay, J W Lewis, J R McCallum, I J MacDonald, A J Merry, P G H T Pollitt, H N Reed, G McM Smibert, B L L Rygate, G A Readett, J P Rogan, S Pickford, B Schneiderman, D H Woodhead, M A Ansari, S Mattingly, A E Smith, W Marshall, A P Bentley, A J F Crossley, J O Doyle, J Hewet, A C Jacob, C S Kirkham, J M Lewis, D R Morgan, M G McEntegart, J T Marcroft, B W Pay, J H S Perrett, A G Quinlan, M R Sheridan, L F Tinckler, D M Zausmer, A Mack Mathewson, J B Lynch, A H Dawes, W Rodger, J F Cogan, C K Brown, F M Parsons, R Pracy, and M J Whelan to be Captains

To be Lieutenants J A Chisolm, E T Dakin, R French, J L Hardman, W Littlestone, J B Morrison, J R S Paterson, J H Pendered, P Rhodes, J R Scholey, J A Stewart, D G A Wesbury, G H Blair, P H Brasher, I W Crown, N H Dray, M J Forth, N M O'C Hewett, W H Lloyd, B W Meade, J N Mickerson, W Peters, P Read, W C D Richards, L F W Rowe, G C Ambrose, C J Burrows, A C Davies, J Davis, J E Drabble, H S Eyre, T J Felix, K M Fergusson, M Harrington, J S H Inglis, C W G Irvine, D P Keith, C A Martin, J M S McCoy, R C MacGillivray, N E Nathanson, A Paton, P Barr-Taylor, W E Watson, F G Anderson, J M Barritt, A J Borkin, J A Carr, E P Cooke, T H Donaldson, N G O Gourlay, R A Hunter, H M Kirkpatrick, M Paneth, J C Phemister, J J Pollock, A I Rowe, M Senk, C H Thompson, J C Turner, W B Waddell, A L Warlow, J R Watson, H H Whincup

## Association Notices

## MIDDLEMORE PRIZE

The Middlemore Prize consists of a cheque for £50 and an illuminated certificate and was founded in 1880 by the late Richard Middlemore F.R.C.S., of Birmingham to be awarded for the best essay or work on any subject which the Council of the British Medical Association may from time to time select in any department of ophthalmic medicine or surgery. The Council is prepared to consider the award of the prize in the year 1949 to the author of the best essay on 'The Value of Orthoptics in the Treatment of Squint'. Essays submitted in competition must reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1 on or before Dec 31, 1948. Each essay must be signed with a motto and accompanied by a sealed envelope marked on the outside with the motto and containing the name and address of the author. In the event of no essay being of sufficient merit the prize will not be awarded in 1949.

## KATHERINE BISHOP HARMAN PRIZE

The Council of the B.M.A. is prepared to consider an award of the Katherine Bishop Harman Prize of the value of £75 in 1949. The purpose of the prize, which was founded in 1926 is to encourage study and research directed to the diminution and avoidance of the risks to health and life that are apt to arise in pregnancy and child bearing. It will be awarded for the best essay submitted in open competition, competitors being left free to select the work they wish to present provided this falls within the scope of the prize. Any medical practitioner registered in the British Empire is eligible to compete.

Should the Council of the Association decide that no essay submitted is of sufficient merit the prize will not be awarded in 1949 but will be offered again in the year next following this decision, and in this event the money value of the prize on the occasion in question will be such proportion of the accumulated income as the Council shall determine.

The decision of the Council will be final.

Each essay must be typewritten or printed in the English language must be distinguished by a motto and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address. Essays must be forwarded so as to reach the Secretary to whom all inquiries should be addressed at B.M.A. House, Tavistock Square, London, W.C.1 not later than Dec 31, 1948.

BIRMINGHAM REGION  
CONSULTANTS AND SPECIALISTS

A meeting of all consultants and specialists in the Birmingham Region to discuss current problems will be held on Friday Sept 24 at 5.30 p.m. at Nuffield House, Queen Elizabeth's Hospital, Birmingham 15.

CHARLES HILL  
Secretary

## Branch and Division Meetings to be Held

NORTH WALES BRANCH—At the Watford Hotel, Ballymore, Wednesday, Sept. 22, 2.30 p.m. Ninety-ninth annual meeting to be addressed by Dr. H. G. D. G. Chairman of Council.

## THE PRESENT POSITION OF NEUROSURGERY IN GYNAECOLOGY\*

BY

ALBERT DAVIS, MD, ChM, FRCS, MRCOG

*Gynaecological Surgeon Prince of Wales's French Dulwich and St Giles Hospitals London*

The advent of autonomic surgery and its specific application by the Lyons School (Leriche, 1925, Cotte, 1925, Molin and Condamin, 1929a) twenty years ago marked an epoch in gynaecology, and since that time a variety of operations mainly designed to interrupt sympathetic pathways from the uterus, but all concerned with the relief of pelvic pain, have been carried out by a variety of surgeons. A sufficient time has now elapsed and a large enough number of cases have been so treated, to allow of assessment of their relative value, and it is my purpose to examine the nature of the procedures involved, their specific indications, and the long-term results of their application. The operations which have survived the initial enthusiasm are presacral, ovarian, and utero-sacral sympathectomy, cordotomy, pelvic alcohol block, and various types of spinal injection, and it will be convenient to discuss these seriatim.

### Resection of the Presacral Nerve

This operation was first described by Cotte in 1925, and has since established itself as the prime pelvic sympathectomy. A logical extension of Leriche's (1925) pioneer periaxillary and lumbar resections, it was based largely on the new conception of the pelvic nervous system arising from Rochet and Latarjet's (1913) brilliant anatomical description of the presacral nerve. They showed that here, in one easily accessible bundle, was concentrated practically the whole sympathetic supply to the pelvis, and that uterine denervation could be accomplished almost completely and relatively easily by resection of this main trunk.

**Rationale**—The sympathetic nerves to the uterus carry motor contractile fibres, so that their section diminishes the muscular spasm which is the basic cause of spasmodic dysmenorrhoea. They also contain the majority of the sensory fibres from the organ, so that their resection will relieve not only the pain of dysmenorrhoea but also that arising from other uterine conditions. It has been shown, too, that in many cases of dysmenorrhoea and uterine carcinoma the pain is primarily due to pathological changes in the peripheral uterine sympathetic nerves (Davis, 1938, Dargent, 1948), division of which removes a constant source of irritation.

**Indications**—The operation is curative in cases of severe spasmodic dysmenorrhoea and is indicated in those patients who remain unrelieved by medicinal treatment, cervical dilatation, and alcohol injection. It is also of great value

as an adjunct to other gynaecological procedures, particularly where pain has been a prominent and long-standing symptom. The pain of pelvic carcinoma, either primary or secondary to radiotherapy, is relieved by this method, but only when it is purely visceral in type, spinal pain is naturally unaffected by sympathetic resection.

### Technique

Absolute relaxation is essential, so that spinal analgesia is the ideal method. In nervous patients the pentothal-curare-cyclopropane sequence is satisfactory. The highest Trendelenburg position is also necessary to secure freedom from bowel interference. The incision is placed in the midline midway between umbilicus and symphysis and need not be more than 1 in (2.5 cm) in length. The Dan to Beersheba gynaecological incision is unnecessary in uncomplicated cases, and serves mainly to convert a relatively minor operation into a major one. The sacral promontory and aortic bifurcation are identified and the posterior parietal peritoneum covering the space between is picked up and incised longitudinally for 2 in (5 cm). The whole of the neuroareolar tissue between the common iliac vessels is systematically separated and gathered into a median bundle, care being taken to strip the under-surface of the peritoneum, to which large nerve bundles are often attached. The presacral nerve is occasionally identifiable as a single narrow cord but it usually consists of several parallel fibres of varying size, so that wide mass dissection is preferable to individual removal. During separation several lateral filaments will be exposed, particularly one from the fourth lumbar ganglion, and these must be divided. The nerve bundle is now elevated with an aneurysm needle and further separated above and below for a distance of 1 in, then divided at each end. This wide excision is necessary to ensure a permanent effect, for regeneration as Haxton (1947) has shown, can be remarkably rapid and complete in sympathetic nerves.

Ligation is unnecessary, any small haemorrhage being controlled by tampon pressure. It is also unnecessary and indeed unwise, to transgress the limits of the operative field for vascular damage is easily accomplished and very difficult to control. The peritoneum is then sutured the pelvis explored, and any minor abnormality corrected.

The operation is relatively easy, and quite safe provided careful attention is paid to the anatomical relations of the area. The ureter occasionally lies near the middle line in this position, and the pelvic mesocolon sometimes transgresses it, but neither abnormality should cause trouble if properly identified. There are also no adverse

\*A postgraduate lecture given at the Chelsea Hospital for Women on Dec 6 1947.

effects apart from an increase in the menstrual flow. The pain of subsequent parturition is in fact much minimized. In Blink (1947) has reported a case of two consecutive painless labours following presacral neurectomy.

#### Results

The prime indication for presacral neurectomy is dysmenorrhoea and it is in this condition that the best results are obtainable. But just how good these are is much disputed and the figures given by different writers reveal very considerable variation. Cotte the inventor of the operation is naturally an enthusiastic advocate and in a recent personal communication states that it is always successful in his hands. Greenhill (1942) is similarly optimistic and Curtis and his associates (1942) are emphatic about the permanence of their cures. Cannon (1937) reports 100% cure in 10 cases. Cannaday (1938) complete or marked relief in 37 out of 40 cases, and Pike (1942) in 14 out of 15. All of De Couvres (1934) 21 cases were cured and similar results in smaller series have been reported by Tirelli (1928), Waters (1946) and others. Some reports are less satisfactory. Counsellor and Craig (1934) in an evaluation of the end results of the Mayo Clinic cases found only nine of 15 cases completely cured, though the remainder were much improved. Meigs (1939) 20 cases of presacral resection alone showed 15 complete cures, two partial and three complete failures and Masson and Shoemaker (1938) obtained only five cures in 10 cases though the remainder were improved. Donaldson (quoted by Bourne and Williams 1945) gives his results in 54 cases as good in 18, fair in 16, and bad in 20, and the experience of Bourne and Williams (1945) leads them to the caustic conclusion that the operation is not so universally successful as some would have us believe.

My own experience covers 86 cases extending over 16 years and the results in later cases show a considerable advance over the earlier. The patients operated on before 1934 showed a cure rate of 54% and those up to 1945 of 71%. Of eight patients operated on since that time, however, only one is not cured and she admits to considerable improvement. This progression is due to a variety of causes—more extensive denervation, more careful peritoneal stripping and more extensive coincident surgery but the main factor has been increased care in the selection of cases. It has now been established that the only dysmenorrhoea for which presacral neurectomy is basically indicated is the primary spasmodic type. Congestive secondary cases may be improved, but the result is always problematical. It is accordingly my practice to limit the operation to those patients suffering from intolerable colicky pain centred over the hypogastrium and in whom all minor and operative measures—exercises, antispasmodics, cervical dilatation and alcohol injection—have failed. Under these circumstances the results achieved are excellent and it is possible practically to guarantee a permanent cure in the properly chosen case.

The importance of careful choice cannot be over-emphasized for it is unwarrantable to subject another wise normal young woman to operation for pain alone without a fair certainty of success. Cases of intractable primary dysmenorrhoea are not common and the average gynaecological surgeon will see perhaps 10 a year. Masson and Shoemaker (1939) found only 15 such cases in 682 cases of dysmenorrhoea—an incidence of 2.2% and though my own figures show the rather higher rate of 4.8% both emphasize the comparative rarity of the indication.

In secondary dysmenorrhoea the operation is less successful and it should not be undertaken for this condition alone. But as an adjunct to operative procedures for the

correction of gross pelvic pathology particularly where pain is a prominent symptom presacral resection is invaluable and should be carried out as a routine in these cases. It is naturally difficult to apportion the pain relief after such composite operations but there is no doubt of the superiority of the combination.

The visceral pain of incurable pelvic carcinoma may be relieved by the operation though the spinal pain often predominant naturally remains unaffected. It is consequently important to make a careful differentiation in each case, and to limit sympathectomy to those with a minimum of somatic pain. Leriche (1939), Todd (1937) and Greenhill (1941) have described the visceral pain as being characteristically diffusely spread over the hypogastrium and lower lumbar region with rectal tenesmus and cystalgia as a frequent accompaniment. Radiation into the thighs and vulva is common but remains diffuse and non-somatic. Somatic pain may present as a girdle pain or be referred along the affected nerves (sciatic, pudendal, obturator) and is usually easily identifiable. True visceral pain is relieved by sympathectomy and Greenhill (1933), who has done most to popularize this application states that it will yield almost perfect results if restricted to appropriate cases. As early as 1933 he reported complete relief in 10 patients suffering from cervical carcinoma, and similar success has been claimed by Wetherell (1933), Prolucci (1928), Pereira (1946), and others. Of Behney's (1934) 21 cases, 16 were relieved for the remainder of their lives over periods from four weeks to 13 months. Other surgeons however have not been so fortunate. Cotte (1936) himself says that pain in the bladder and rectum is not always relieved. Atlee (1935) was successful in two out of five cases, and Dargent (1948) in one out of three. Verbruggen (1940) says that relief is obtained only while the growth is limited to the body of the uterus while Cutler (1938) states that only 50% of cases will show a good result in spite of the loud clamour of the gynaecologists.

My own experience in eight patients has not been encouraging. The operation was technically impossible in two because the malignant mass encroached on the promontory, in two the pain was unaffected, one was slightly relieved (this might easily have been psychological), and the remaining three were definitely improved though for only three weeks in one of these. Such failure is probably explained by several factors. Pathological change in the sympathetic nerves adjacent to a carcinoma is early and extensive (Pereira 1946, Dargent 1948, Jiano *et al.* 1928) and may have already spread proximal to the operative site. Sensory impulses might also be conveyed by way of the lumbar sympathetic chains and the sacral parasympathetics both of which remain intact and high lymph nodes may cause local pressure on the lumbar and thoracic cords. These same trunks may also be the site of interstitial sclerosis—a common result of deep radiotherapy and this intraneural pressure is undoubtedly a cause of intractable neuralgia referred to the pelvis. Too much should therefore not be expected in these cases but in suitable patients the operation is well worth a trial.

#### Ovarian Sympathectomy

In some cases of dysmenorrhoea the cause of the pain is ovarian as shown by its characteristic distribution, its persistence after uterine denervation and its elicitation on bimanual compression. For this syndrome which Browne (1939) states accounts for nearly 12% of all cases of dysmenorrhoea he advocates section of the ovarian nerves. The operation has also been applied successfully to cases of severe ovulation and as a palliative in ovarian endometriosis.

**Technique**—The ideal operation postulates a systematic dissection of the ovarian nerves as they lie within the folds of the infundibulo-pelvic ligament, but this is rarely possible, for they lie intertwined with the complicated ovarian venous plexus, and haemorrhage is an invariable accompaniment. Apart from obscuring the operative field, this is usually uncontrollable by individual ligation, so that the ligament itself must be tied at a higher level. The only practical procedure, therefore, is to divide the whole ligament near the pelvic brim after mass ligation, and this is the one generally adopted.

**Results**—There is no doubt of the value of the operation in some carefully selected cases. Browne reports cures in 10 of 16 patients with ovarian dysmenorrhoea, and though most surgeons will disagree with his estimate of the frequency of the condition the occasional case encountered is gratifyingly relieved. The operation is also useful as an adjunct to conservative operations on the adnexae, particularly where pain has been a marked factor, as in endometriosis, and I have had good results in three such cases. Severe ovulalgia—"mittelschmerz"—is a rare condition, and is due to tubal hypercontraction, excessive follicular spill, or pressure on the circular nerves which embrace the distended follicle (Davis, 1939). Where this last factor is the cause ovarian denervation gives an immediate and surprisingly complete cure.

It is, however, questionable whether the advantages of this operation outweigh its possible dangers. It certainly delays follicle development in dogs, and, though the hormonal function of the human ovary appears to be independent of its nerve supply, the latter is so rich that it must be assumed to have some important controlling role. Interruption of the main vascular supply to the organ must similarly exert an adverse effect on its function. The operation should therefore not be undertaken in young non-parous women, except for the most urgent indication, and should generally be reserved for the few selected types described above.

#### Alcohol Injection of the Pelvic Plexus

This operation was originally introduced (Davis, 1936) with the object of blocking the nerve pathway to the uterus at its nearest externally accessible point.

**Rationale**—The pelvic plexus is the main uterine ganglion, receiving the bulk of the nerve supply designed for that organ. It is formed by the confluence of the inferior hypogastric plexus and the nervi erigentes, the former carrying abdominal sympathetic and the latter sacral parasympathetic fibres, and the nerves are distributed to the uterus in the form of several fine strands emerging from the anterior border of the plexus. It thus presents an ideal site for direct and complete interruption of these pathways, for practically the whole of the uterine nerve supply is here concentrated in a comparatively small area.

The plexus is a large flattened mass of nervous tissue lying in a fairly compact sheet at the side and in front of the ampulla of the rectum. From here it stretches forward to the uterus in the form of long tough fibres which enter the organ just above the cervix. It lies immediately beneath the floor of the pouch of Douglas at its postero-lateral angle and above the corresponding lateral vaginal fornix, the lowest part being contained within the folds of the utero-sacral ligament. The ureter crosses its superior border, and the uterine artery lies close to its lateral surface, the internal iliac vessels passing behind and below.

**Indications**—The method is primarily of value in cases of severe spasmodic dysmenorrhoea which have failed to react to medical treatment. In these it should be combined

with cervical dilatation, which, as I have shown elsewhere (Davis, 1933), is itself a type of sympathectomy, for the external os is surrounded by a circular sympathetic plexus rupture of which is the basic factor in the pain relief obtained by this simple procedure. It is also indicated in cases of painful parametritis and vaginal neuralgia, and as an adjunct to cervical cauterization in Young's syndrome of iliac-fossa pain.

**Technique**—Under intravenous anaesthesia the cervix is pulled to one side and the opposite lateral fornix exposed by retraction. A strong spinal needle is inserted into the vaginal mucosa at its highest point, 1 cm lateral to the cervix. The needle is then passed laterally and posteriorly at an angle of 45 degrees to both the vertical and the horizontal planes for 2 cm, being guided to the side of the rectal ampulla by a finger placed in that organ. The needle is then withdrawn for 0.5 cm and, after preliminary aspiration, 1 ml of absolute alcohol is slowly injected, the point being kept moving throughout. The needle is then almost completely withdrawn and reinserted into the lateral parametrium just by the side of the supravaginal cervix and a further 1 ml infiltrated into this area. This last injection, originally advocated by Blos (1929), effectively deals with any fibres which have escaped the original block. The whole procedure is then repeated for the other side. It is important to avoid perforation of the rectum, for cellulitis may follow. This is avoided by keeping the needle-point 0.5 cm from the organ, as determined by the internal finger. Both the ureter and the uterine artery are medial to the operative field, but constant movement of the needle-point will eliminate the danger of damage to these structures. The amount of alcohol employed is also important, for if the suggested quantity is exceeded there is danger of complete destruction of the plexus, with subsequent urinary retention, for the motor fibres in its upper portion are indispensable for normal bladder function.

**Results**—Of 61 cases of primary spasmodic dysmenorrhoea recently reviewed 43 (nearly 70%) were permanently and adequately relieved (It should be mentioned that five of these had the injection repeated for recurrence after a short interval, but the effect of the second operation was permanent). Eleven patients were relieved to the extent that the subsequent periods, though still painful, were tolerable, and in the remaining seven there was no appreciable change. These results, though far from perfect, show a considerable advance on those obtained from simple cervical dilatation, which cures an average of 20% of patients, and the operation should be utilized for all primary spasmodic cases which remain unrelieved by medical and physiotherapeutic measures.

#### Intrathecal Alcohol Injection

Intraspinal alcohol injection was introduced by Dogliotti in 1931 for the relief of intractable neuralgia, and it has since been applied successfully by Stern (1934), Greenhill and Schmitz (1936), Todd (1937), and others to cases of cervical carcinoma.

**Technique**—The patient lies on the side, with the body inclined to the prone position and the back arched as much as possible. The table is tilted to an angle of 15 degrees, the head end being lower. A procaine wheal is raised over the interspace between the fourth and fifth lumbar spines and a spinal needle inserted into the subarachnoid space. Absolute alcohol is then injected very slowly to a total quantity of 0.5 ml without admixture of cerebrospinal fluid. The patient remains in the same position for an hour before being returned to bed, and the whole procedure is repeated for the other side after an interval of 10 days.

The method is an extremely easy one, requiring the minimum of preparation and apparatus and it has the additional advantage (as emphasized by Greenhill) of being applicable to bed ridden patients at home. But it carries several disadvantages: incontinence of faeces and urine is a not infrequent sequel and other paralytic complications resulting from cord damage are occasionally seen. The operation is therefore restricted to cases of inoperable carcinoma. Complete relief of pain is also by no means guaranteed in spite of the somewhat optimistic reports of some of the earlier workers (Saltzstein, 1934; Stern, 1940) and it is noteworthy that Greenhill (1947), one of the pioneers in this field, has reduced his estimated relief rate from 92% in 1935 to somewhat "more than half" in 1947. However when the operation is successful the completeness and permanence of the pain relief are extremely gratifying and the patient is in addition saved from the depression and mental stultification incidental to prolonged morphinization.

Subarachnoid alcohol injection is therefore indicated in all cases of visceral pain arising from incurable pelvic carcinoma. I have recently advocated reinforcement of this procedure with simultaneous alcohol injection of the pelvic plexus, and the combination, where practicable, seems to give considerably better results.

#### Intraspinal Sulphate Injection

To circumvent some of the difficulties inherent in alcohol injection Bates and Judovich (1942) substituted magnesium sulphate. While adequately destructive to nervous tissue it is much less so than alcohol, and therefore may be used in larger quantity and over a greater area.

The *technique* consists in the intraspinal injection of 250 mg of ammonium sulphate dissolved in 5 ml of sterile water after preliminary spinal procaine analgesia to minimize the pain of injection. The third interspace is employed, and the patient subsequently sits up to allow of gradual diffusion of the heavy solution.

The originators of this method are optimistic of its permanent benefit, but in two personal cases the pain of injection was worse than the original complaint, and in neither was there a reasonable degree of subsequent relief. Bourne and Williams (1945) cite similar disappointing results in their own cases, but, as they state, it is yet too early to form a final opinion, particularly as other workers have been more favourably impressed.

#### Section of the Utero-sacral Ligaments

This is the original pelvic sympathectomy, and was first advocated in 1899 by Jaboulay, who ruptured the pelvic parasympathetic nerves by serum injection and blunt dissection of the retrorectal space. It was at first received enthusiastically, but rapidly fell into desuetude as the result of the frequent and severe complications following the somewhat crude avulsion technique of the earlier surgeons. The operation was revived and modernized by Condamin in 1927 and since then this worker, together with Molin, has published several reports describing excellent results in a variety of painful pelvic conditions.

*Rationale*—The posterior parametrium of the utero-sacral folds contains the utero sacral ligaments proper, some smooth muscle, fine blood vessels and lymphatics, and numerous nerve bundles lying in loose fibro-fatty areolar tissue. The nervous element consists of the lower border of the pelvic (Lee Frankenhauser) plexus and its forward branches to the uterus and so comprises the main supply to that organ. These postganglionic nerves are easily accessible in the anterior part of the utero-sacral ligament and intervention at this level would appear to be the ideal uterine sympathectomy.

*Technique*—The ligaments may be divided from above but this is justifiable only when laparotomy has been performed for the correction of some basic pathology. Otherwise the vaginal approach is indicated. In this the posterior lip of the cervix is seized with vulsellum forceps and pulled downwards and forwards so as to put the utero sacral ligaments on the stretch. A semicircular incision is made through the vaginal epithelium at the level of the cervico vaginal junction from the base of one broad ligament to the other. The subjacent parametrium behind the uterus is separated by finger-swab pressure, leaving the utero sacral ligaments free and more clearly defined. They are then cut away with scissors from their somewhat wide insertion into the uterus, and the free ends further separated by blunt dissection to prevent subsequent regeneration. The operation is technically very simple, but haemorrhage from small vessels is usually troublesome and difficult to control. Ligation is complicated by retraction of the cut end, and the tedious swab pressure required is a poor substitute. Sometimes this is quite ineffective, and blood collects in the posterior parametrium, forming a large haematoma which usually becomes infected.

*Indications*—Utero sacral resection is of value in intractable dysmenorrhoea, but is mainly indicated for the relief of what may be called the "posterior parametritis syndrome." The basic pathology of this condition is a utero-sacral lymphangitis secondary to cervicitis, with diffuse inflammation, perineural sclerosis, and smooth muscle spasm. The prime resulting symptom is chronic low backache aggravated by walking, menstruation, and coitus, and examination reveals the tender, contracted cord-like ligaments.

*Results*—The efficacy of the operation is controversial. Louros (1927) obtained 12 cures in 14 patients with posterior parametritis, Molin and Condamin (1929a) give no definite figures, but claim success in "the majority" of cases, and Freund (quoted by Cotte, 1929) in a review of the literature states that on the whole the results are satisfactory. Schockaert (quoted by Cotte, 1929), on the other hand, gave up the procedure after six attempts, in none of which was he successful in producing the slightest symptomatic benefit, while Molin and Condamin (1929b) have reported two cases of subsequent re-formation of the divided ligaments by a painful fibrous band, so that the patients were actually worse than before. Cotte (1929) reports similar failure in 12 cases. This discrepancy is probably due to variation in the depth and extent of the sympathectomy. The nerves are distributed over a fairly wide area within the utero sacral folds, and unless the dissection is thorough the majority will escape intact. Most surgeons are chary of this type of blind manoeuvre, and are inclined to limit it to the visible minimum, with the result that the actual neurectomy is a relatively small one. Individual anatomical variations also undoubtedly play a part. My own results in four cases have been disappointing, probably as a result of these factors.

In spite of these deficiencies, however, utero sacral resection retains some of the best features of the ideal sympathectomy, for it is an easy, minor, and relatively safe procedure. In carefully selected cases, and after preliminary procaine analgesia to test the ultimate result, its efficacy is undoubted, and if the dissection is kept well forward there should be little danger of inclusion of vesical or rectal filaments or of damage to the ureters and uterine arteries. Remote complications are rare for menstruation, pregnancy, and parturition are unaffected and as the ligaments appear to play little part in supporting the uterus (Segond 1926) prolapse is not a sequel. The operation therefore seems worthy of more extended trial.

### Utero-sacral Alcohol Injection

This is a good though temporary substitute for resection, and is indicated for the same conditions. It is also a useful adjuvant to pelvic plexus injection, catching any filaments that may have escaped the primary needle.

The technique is simple, and consists merely in the injection of 0.5 ml of absolute alcohol into the uterine end of each ligament, identified by strong anterior traction on the cervix. The alcohol must be placed superficially, to avoid involvement of the adjacent ureters, and medially, to escape the uterine vessels.

I have found this procedure particularly valuable in cases of painful utero-sacral spasm complicated by coitus interruptus. The dyspareunia disappears immediately and relief of the spasm allows of resolution of the contained subacute inflammation.

### Epidural Block

Epidural procaine analgesia, used extensively in obstetrics, has been employed with moderate success in cases of uterine carcinoma by Todd (1937) and, more recently, by Kenny (1947), the latter using a long-lasting preparation.

**Technique (Kenny)**—With the patient in the left lateral position the skin and deep tissues over the caudal opening of the sacral canal are infiltrated with 2% procaine. A stout 3-in (7.5-cm) needle is directed to the aperture at an angle of 45 degrees to the skin and the fibrous membrane covering it pierced, the needle is then depressed to an angle of 15 degrees and pushed steadily on until about 1 in (2.5 cm) of its length is lying freely movable within the canal. Then 50 ml of warmed procaine (a 1.5% solution of procaine in arachis oil) is very slowly injected, the procedure lasting about 10 minutes.

This method has the advantage of relative safety, but anatomical variation in the configuration of the sacral canal often makes the approach difficult and sometimes impossible. In addition the relief obtained is generally of short duration, though Kenny's results show that the prospects of more permanent amelioration are better when longer-acting analgesics are employed.

### Paravertebral Block

It has been shown experimentally by Cleland (1933) that the afferent sympathetic fibres from the uterus enter the cord through the 11th and 12th thoracic roots, and that section of the corresponding roots and their rami communicantes in dogs has no apparent adverse effect on parturition. Shumacker noted by chance that a patient with bilateral lumbar sympathectomy underwent an almost painless labour, and he and his colleagues (1943), Jarvis (1944), Cleland, and others have since produced a similar analgesia by procaine block of the sympathetic chain at the level of the first and second lumbar ganglia. (The method was originally described by Dellapiane and Badiano in 1927, and the credit of originality must be given to these workers, but unilateral block only was then advocated, with correspondingly incomplete effect.)

**Technique**—With the patient sitting up and bent forward a spinal needle is inserted at a point 5 cm lateral to the first lumbar spine. It is then inclined inwards towards the spine at an angle of 60 degrees to the skin and passed between the transverse processes of the first and second lumbar vertebrae until the vertebral body is touched. The depth of this point varies from 7 to 11 cm (Jarvis), but it is fairly easily identified. The needle is then straightened to an angle of 90 degrees to the skin and passed by the side of the body for a further 1.5 cm, 2.5 ml

of a 2% solution of procaine is injected into this area after aspiration and the whole procedure repeated on the other side. As a rule it is only necessary to block the second ganglion, but in cases presenting technical difficulty or in which analgesia is imperfect the third and fourth should also be done (Flothow, 1935).

The great disadvantage of this procedure is its impermanence, for the longest period of analgesia obtained is two hours. During labour it can, of course, be repeated and adequate relief provided, but for the generality of painful conditions this temporary analgesia is obviously useless. Its main indication would seem to lie in the determination of whether pain is of visceral origin or not. If the pain of dysmenorrhoea, pelvic neuralgia, or carcinoma is abolished by paravertebral analgesia it will very likely be permanently relieved by presacral neurectomy, if not, the operation is contraindicated.

Paravertebral alcohol injection in the same situation has been suggested by Pereira (1946) for the relief of neuralgia secondary to pelvic malignancy, but as yet no surgeon has been intrepid enough to attempt it. In quite hopeless cases, however, where the expectation of life is very short the method might well be worthy of trial.

### Cordotomy

Section of the lateral spino-thalamic tracts, one of the earliest neurosurgical procedures, is advocated by Shannon (1945) as the ideal operation for pain due to pelvic carcinoma. Complete and permanent relief is certainly ensured by this procedure, but, involving as it does a tedious laminectomy and delicate intraspinal manipulation, it is doubtful whether the operation is applicable to any but a very few cases.

### Conclusions

The initial enthusiasm with which most of the operations discussed above were greeted was bound to provoke a compensatory disappointment, particularly when it was found that pain of all types was not inevitably cured by sympathectomy. But the third phase of critical analysis has now been reached, and this leaves no doubt of the permanent value of these procedures. They are themselves easy of performance: the secret lies in careful case selection. Given this, and the equally careful application of the appropriate operation, the great majority of cases of pelvic pain can be adequately relieved in one way or another, and it is more than justifiable to give these patients the benefit of such relief. Too many women suffer from much unnecessary pain, and the results of sympathectomy are now good enough to warrant its more extended application.

## PETHIDINE AND SCOPOLAMINE IN LABOUR

III

HILDA ROBERTS, MRCS, DA DCH

Registrar in Anaesthetics Obstetric Department Postgraduate Medical School of London

Pethidine and scopolamine have been used for obstetric analgesia in the obstetric department of the Postgraduate Medical School of London during the past two years. Scopolamine was employed in addition to pethidine in order to secure a more certain analgesia than can be obtained with pethidine alone. The experience of others has demonstrated the safety of pethidine but at the same time it has become apparent that in a relatively high proportion of cases the analgesia induced by it alone may be inadequate (Barnes, 1947; Cripps, Hill, and Haultain, 1944; Gillen and Prescott 1944).

Our aim has been to provide rest and sleep during the latter and more painful part of the first stage of labour and to give relief during the second stage without impairing the patient's power of co-operation. There has been no hesitation in complementing the pethidine and scopolamine with gas and air or trilete inhalations if necessary during the second stage or during the actual delivery. There were 2,651 deliveries in the department from Oct 1 1946, to Dec 1 1947 and in 885 of these the mothers received pethidine and scopolamine. 500 of the latter group were personally observed and these form the material of this communication.

Except for five cases of toxæmia of pregnancy, one patient with hydramnios and mitral stenosis and two cases of mild ante-partum hæmorrhage of undetermined origin, all the cases were normal. We do not regard pethidine and scopolamine as contraindicated in toxæmia. In fact it is only in eclamptic cases that pethidine and scopolamine are not given because these need a more intensive sedation.

The 500 cases include four twin pregnancies and one set of triplets making 506 infants in all. There were 378 primiparae and 122 multiparae.

### Dosage

When the administration of pethidine and scopolamine was first introduced into this department the following rules were laid down for guidance: (1) Labour must be established before administration of analgesia. Uterine contractions must be of good amplitude and occur at regular intervals. (2) Dilatation of the os uteri must have reached at least three fingers in a primipara and two fingers in a multipara.

The first dose consists of pethidine, 100 mg, and scopolamine, 1/150 gr (0.43 mg), intramuscularly. A second similar dose is given one hour after the first but its administration must be judged according to the merits of each case and in relation to (a) the rate of dilatation of the os uteri, and (b) the degree of dilatation one hour after the first dose. If the os is rather more than three quarters dilated it is not advisable to give the dose unless pethidine alone is given.

Subsequent doses can be given at intervals of four to six hours; however, if possible scopolamine is not given within two hours (at least) of delivery, as it may promote some non-cooperation of the mother and some respiratory depression of the infant. The maximum dosage of scopolamine in this series was three doses each of 1/150 gr, and it was given over a period of 18 hours together with 400 mg of pethidine. The labour lasted 33 hours altogether. It has been found that the intervals between the doses are lengthened as time and labour go on, the amount and frequency varying with each patient. The maximum amount of pethidine used in a single case in this series was 500 mg, and this was given over a period of 30 hours together with two doses of scopolamine, each of 1/150 gr.

### Route of Administration

The drugs were generally given intramuscularly, but if the patient was suffering unduly and immediate relief was required the first dose was given intravenously, at least three minutes being taken over the injection. Subsequent doses were given intramuscularly. Schumann (1944) recommends intravenous administration if the patient is expected to be delivered in two hours. For three months pethidine has been administered intravenously at full dilatation of the os and also in the second stage up to within 10 minutes of delivery, without adverse effect on the foetus. The dose of 100 mg is diluted with either sterile distilled water or sterile normal saline to double its former volume and is given over a period of three minutes or more to avoid the subjective symptoms of nausea, vomiting and dizziness. This was used to show that women need not be deprived of adequate relief from pain although they might be well advanced in labour on admission to hospital, and this method was found to be very satisfactory. The patient is eased of her pain to a marked degree, and gas and air or gas and oxygen is given during the delivery if necessary.

Two years continued use of pethidine and scopolamine as an analgesic during labour has shown that a large percentage of the cases require only the first dose or the first dose plus 100 mg of pethidine one hour later. An analysis of the dosage given to the 500 cases is shown in Table I. It will be seen that the majority of cases required only the smaller doses of pethidine and scopolamine; this is particularly noticeable in the multiparae although at least 13 primiparae who received pethidine 100 mg, and scopolamine, 1/150 gr would have benefited from another dose of 100 mg of pethidine.

TABLE I—*Dosage*

Pethidine	Scopolamine	Primiparae	Multiparae
100 mg	1/150 gr	153	70
100	1/100 ,	77	33
200	1/150 ,	75	8
200	1/100	19	6
200	1/150 (twice)	26	5
300	1/150	12	
300	1/150 (twice)	6	
300	1/150 , (twice)	3	
400	1/150	2	
400	1/150 (twice)	3	
400	1/150 (thrice)	1	
500	1/150 (twice)	1	

**Degree of Analgesia Obtained**

The degree of analgesia obtained has been classified as follows

**Good**—This includes (a) complete relief from pain and complete amnesia (b) complete relief from pain and partial amnesia, and (c) almost complete relief from pain and no amnesia

**Satisfactory**—Here the pain was relieved to such an extent that although the patient could feel it to a mild degree her labour seemed easy

**Fair Only**—In this group the patient gained some relief, but not enough to make the labour easy. Frequently this was due to the fact that the patient had not received enough pethidine and scopolamine, these cases are mainly primiparae who had pethidine, 100 mg, and scopolamine, 1/150 gr, only, and occurred in our early trials

All the patients came under one of these headings, so that all of them obtained some relief (Table II). This classifica-

TABLE II—*Degree of Relief Obtained*

Relief Obtained	Primiparae	Multiparae
Good	306	105
Satisfactory	55	14
Fair only	16	2
Difficult to assess	1	1

tion of the degree of relief has been compiled from personal observations of the patients during labour and from their own opinion the next day when questioned. They were encouraged to describe the relief in their own way, and not to give answers to leading questions. The two cases under the heading "difficult to assess" are here described.

A 1-para aged 31 was hysterical on admission. She became settled for a few hours after an intramuscular injection of pethidine, 100 mg and scopolamine, 1/150 gr, but at full dilatation of the os she became unmanageable again and a forceps delivery was necessary.

A primigravida aged 33 was hysterical on admission. She slept after an intramuscular injection of pethidine, 100 mg, and scopolamine 1/150 gr. The pethidine was repeated with effect. However she became very uncooperative on reaching the second stage of labour and forceps were applied because of this.

**Co-operation of the Patient during Labour**

The majority of the patients were co-operative, and even though a large proportion of them were sleepy in the second stage they would "push down" when encouraged. However, it was noticed that patients allowed to lie quietly on their side would push down automatically when the second-stage pains occurred even though they were very sleepy, and labour proceeded without any encouragement from the midwife.

An analysis of the varying degrees of co-operation in the 500 cases showed that 466 patients were co-operative, 27 fairly co-operative, and 7 non-cooperative.

Of the 27 fairly co-operative patients nine became non-cooperative and tired in the second stage where mechanical difficulties impeded the advance of the head and all ended

as forceps deliveries, one was a primipara breech delivery, 16 would have been more co-operative if more pethidine had been given to increase the degree of analgesia, and one had had three 1/150-gr doses of scopolamine, which is regarded as a large amount, and she was completely disorientated.

The 7 non-cooperative patients were as follows. One was a Russian who did not speak English. The foetal head was held back by a rigid perineum. When questioned the next day she did not remember anything of her labour. One had a reaction to scopolamine although only two 1/150-gr doses were given. Two were hysterical on admission, and have been described. Three had a reaction to scopolamine after only one dose of 1/150 gr. They had complete amnesia.

**The Excitement Factor in Scopolamine Administration**—It has been explained that four cases were non-cooperative during labour owing to the administration of scopolamine. In these cases the dosage was comparatively small. Three other patients were completely disorientated during the first stage of labour and tended to wander about the labour ward, but they were quite amenable to treatment and have been grouped under the heading of "fairly co-operative" in the second stage. It has seemed to me that the patients who became excitable after the administration of scopolamine were those who had a naturally excitable nature. Therefore the scopolamine is given according to the temperament of the patient and her reaction to the first dose. Complete amnesia is not the object of good analgesia, in fact, it is best if the mother can remember the major part of the labour. The most satisfactory result is where she realizes what is happening but does not feel the pain. Scopolamine is given only to increase the effect of the pethidine and not to produce the marked amnesia of the old twilight sleep.

**Condition of the Infants at Birth**

Since the introduction of pethidine and scopolamine into the obstetric department of this hospital there has not been an increase in the foetal mortality, and in cases of foetal morbidity the cause could not be attributed to the analgesia given during labour. Among the 506 infants there were three foetal deaths and 37 cases of foetal asphyxia.

**Foetal Deaths**—There were two stillbirths and one neonatal death. One stillbirth, the second of twins, had a very rapid delivery, breech presentation, the first twin was in good condition. The other stillbirth was involved in a long second stage (3 hours 20 minutes) and the cord was tightly round its neck. The mother had had 400 mg of pethidine and two 1/150 gr doses of scopolamine over a period of 20 hours. The last dose of pethidine was given 3 hours 35 minutes before delivery. The neonatal death occurred in a premature infant of 34 weeks, it was very feeble at birth and lived only 11 hours.

**Foetal Asphyxia**—There were three cases of "white asphyxia" and 34 cases of "blue asphyxia". The cases of "white asphyxia" were as follows: (1) The mother was the Russian referred to above. Pethidine 200 mg, and scopolamine, 1/150 gr, was given. (2) There was a show of meconium-stained liquor in the early stage of labour although the foetal heart was satisfactory until the end of the second stage. (3) This case was due to a very rigid perineum. All three recovered in a few hours. The "blue asphyxia" babies were quiet at birth and rather slow to breathe, or respiration was impeded by the presence of mucus in the air passages. Thus any baby who did not breathe and cry spontaneously at birth has been included in this group. They all recovered completely within 10 minutes. The probable causes of the asphyxia were as follows: prematurity, 4, cord round the neck several times, 4, rigid perineum, 2, forceps delivery for some mechanical obstruction, 11, triplets, 1, and mucus in the air passages in considerable quantities 10. The maternal mortality was nil. However, some patients suffered from either all or some of the

subjective symptoms which occur after the administration of pethidine—i.e. nausea, vomiting and dizziness—but the proportion was very small. There were no other reactions suggesting idiosyncrasy to pethidine.

### Effect on Length of First and Second Stages

Comparisons have been made between the length of the first and second stages of normal cases receiving pethidine and scopolamine analgesia and similar patients having only gas and air or trileine inhalations. They have been classified

TABLE III—Duration of Labour

Date	No.	Mean Hours	Difference Between Means	S.D. of Diff Between Means	t
<i>Primiparae First Stage</i>					
1944-5 Gas etc.	816	15.92	3.04	0.57	5.33†

<i>Primiparae Second Stage</i>					
1944-5 Gas etc.	816	1.005	0.016	0.040	—*
1946-7 Gas etc.	563	0.989			
1946-7 Pethidine and scopolamine	619	1.107	0.120	0.044	2.73†
<i>Multiparae First Stage</i>					
1944-5 Gas etc.	946	9.17	1.29	0.31	4.16†
1946-7 Gas etc.	737	7.88			
1946-7 Pethidine and scopolamine	199	11.06	3.18	0.54	5.89†
<i>Multiparae Second Stage</i>					
1944-5 Gas etc.	946	0.323	0.012	0.105	—*
1946-7 Gas etc.	737	0.335			
1946-7 Pethidine and scopolamine	199	0.381	0.046	0.024	1.92*

\* Not significant † Significant at 1% level

is follows: (1) All cases receiving pethidine and scopolamine between Oct 1, 1946, and Dec 1, 1947. (2) Patients having gas-and-air or trileine inhalations only during the same period of time. (3) Patients receiving gas-and-air or chloroform, using the Young Simpson inhaler, between Oct 1, 1944, and Dec 1, 1945 during this time pethidine and scopolamine were not used in the department. Each group has been divided into primiparae and multiparae. The results are shown in Table III.

The four groups of patients seem to follow much the same pattern, and will be considered together. The significant difference between the mean of 1946-7 patients receiving gas, etc., and that of the 1946-7 patients receiving pethidine and scopolamine seems at first to show that the latter combination lengthens labour. But the difference between the mean of 1944-5 patients receiving gas, etc., and that of 1946-7 patients receiving gas, etc., suggests that in fact the 1946-7 patients receiving gas include an unduly large proportion of short labours. Hence the pethidine-and scopolamine group contains a correspondingly increased proportion of cases of long labour. When the 1944-5 patients are compared with the combined 1946-7 patients, it appears that the combined mean labour time of the latter would be less than that of the former. Thus there is a suggestion that pethidine and scopolamine in fact have the effect of *shortening* labour, if anything. To prove this an experiment designed to show up this effect on its own would be required.

The length of the third stage in the 500 deliveries has been grouped and is shown in the form of a graph (Fig 1). The incidence of post partum haemorrhage was 15, two

following forceps deliveries, and there were three retained placentas requiring manual removal.

### Other Effects

**Effect on Uterine Contractions**—In order to investigate the effect of pethidine and scopolamine on the frequency and amplitude of uterine contractions recordings were made on a kymograph with the aid of an abdominal

FIG 1—Showing the duration of the third stage of labour in 500 cases

tambour. The abdominal method was used in preference to the intrauterine in order to avoid any false stimulus to the uterus. In some cases the recordings showed a lengthening of the time interval between the first two or three contractions after the injection of pethidine and scopolamine, but there did not seem to be any alteration of rhythm or amplitude. The patient became quieter and

FIG 2—Showing the uterine contractions during the first, second, and third stages of labour in a primipara. The relief obtained after the injection of the pethidine and scopolamine was good, the patient was co-operative in the second stage, and the baby was in good condition at birth. The third stage was normal.

slept after the injection, so there were fewer extrauterine excursions recorded on the drum and the picture presented a smoother appearance. When a recording was being made the majority of the initial doses were given intravenously in order to produce the maximum effect in a short time. Figs 2 and 3 are typical of the results obtained from 35 patients.

FIG 3—Showing the uterine contractions of the first, second and third stages in a multipara. The patient co-operated well, the baby cried before the shoulders were born, the placenta was expelled satisfactorily, and effective analgesia was obtained.

**Blood-Pressure Changes**—In a number of cases blood-pressure readings were taken at intervals of one and two minutes before, during, and after the administration of pethidine and scopolamine, some patients being given intravenous injections and some intramuscular. These records show a short elevation varying between 5 and 30 mm Hg in the systolic and a smaller rise in the diastolic pressure. After 10 minutes the blood pressure returned either to normal or to a slightly lower level (Fig 4). Hori and Gold (1944)

FIG 4—Typical graph showing blood pressure changes on intravenous administration of pethidine and scopolamine during labour

found that pethidine and scopolamine caused a fall of 40 mm Hg in the systolic pressure and an acceleration of the pulse rate when given intravenously. Perhaps these occur with rapid intravenous injection, as such fall in blood pressure and rise in pulse rate are common to any form of rapid intravenous assault.

**Respiratory Changes**—According to Batterman and Mulholland (1943) respiratory depression is rare in patients treated with ordinary doses of pethidine. In the present series no maternal respiratory depression was noticed and Fig 5 shows the respiratory excursions of a

FIG 5—Showing the respiratory excursions before and after administration of pethidine and scopolamine. When the patient was sleeping the abdominal respiratory movements were quieter but she showed no signs of respiratory depression.

patient who had received pethidine and scopolamine. These are typical of the results obtained.

**Incidence of Forceps Deliveries**—In the 500 cases there were 23 forceps deliveries. The reasons for instrumental

delivery were: obstetric causes, 19; maternal distress, 3—2 were hysterical and 1 was of pre-eclamptic toxæmia; and foetal distress, 1—on delivery it was found to be a deep transverse arrest and a lateral placenta prævia. Meconium-stained liquor was the first indication of foetal distress. In none of these cases could the application of forceps be said to be due to the analgesia.

### Conclusions

Observations made on the analgesic effects of pethidine and scopolamine during labour have shown that this method is very effective in relieving the pains of childbirth. Provided that labour is established and the dosage is given according to the stage and the rate of progress of the labour no untoward results occur. The addition of scopolamine increases the effect of the pethidine, and its usefulness far outweighs the very occasional excitement which may occur. If the dose of scopolamine is small, co-operation can be elicited from most patients in the second stage with a little encouragement from the midwives. The fact that the midwives working in the labour ward in this hospital have been and are most enthusiastic about the administration of pethidine and scopolamine during labour shows that their work has not been complicated by uncooperative patients and asphyxiated babies.

The results from both the maternal and the foetal aspects are gratifying, and a large number of women have expressed their delight at childbirth being made so pleasant. It is important to emphasize that the amount of pethidine and scopolamine given should be the minimum that will afford effective relief, and each patient is judged according to her reaction to the first dose. Encouraging words and an explanation of what is being done go a long way towards making the analgesia a success.

### Summary

A series of 500 cases receiving pethidine and scopolamine during labour have been observed. The degree of relief obtained was good in 82.2%, satisfactory in 13.8%, and fair only in 3.6%. Two patients were difficult to assess. The results do not show any increase in either maternal or foetal mortality rates, and the incidence of post-partum hæmorrhage is not raised.

I would like to express my gratitude to Professor James Young for permission to publish these cases and for the advice and encouragement he has always given. I am indebted to my assistant, Sister K. Kane, midwife analgesist to the department, whose conscientious and loyal help has made this investigation possible, and to the nursing staff of the labour ward, who have shown themselves anxious to relieve the pain of childbirth. My thanks are due to Dr. Wootton, of the Department of Biochemistry, for help and advice with statistics.

The International Hospital Federation has invited Capt J. E. Stone, consultant on hospital administration and finance to King Edward's Hospital Fund for London, to become honorary secretary and treasurer, and the Fund has agreed. The Federation's secretariat will be established temporarily in the Fund's offices at 10, Old Drury, London, E.C.2. The Federation is an international organization established to collect national literature on hospital work and hold congresses, set up commissions, and publish reports in order to improve hospital development and administration. The first international hospital congress will be held in Holland in June, 1949.

## COELIAC DISEASE\*

BY

WILFRID SHELDON, MD, FRCP

Physician to the Hospital for Sick Children  
Great Ormond Street Physician in Charge  
Children's Department King's College Hospital

Few conditions in childhood have maintained their challenge more persistently than has coeliac disease. A satisfactory explanation of the fault that underlies this malady has yet to be made, the course is long, usually extending over years, treatment is apt to be a prolonged trial to all concerned, and the eventual outcome is by no means invariably satisfactory, for, apart from a mortality rate of roughly 10%, in those who survive some permanent dwarfing of height may be a legacy, and in a few cases steatorrhoea may continue into adult life.

## Coeliac Syndrome

Coeliac disease is not the only cause of steatorrhoea in young children. Occasionally if tuberculous infection of the mesenteric glands is sufficiently widespread mechanical interference with fat absorption may lead to steatorrhoea the stools closely resembling those of coeliac disease, and in addition there is likely to be both wasting and some degree of abdominal distension. The history, the presence of palpable gland masses in the abdomen, the response to tuberculin skin tests, and perhaps the evidence of calcification in the mesenteric glands in the x-ray film will, however, facilitate the differential diagnosis.

Steatorrhoea with diarrhoea and some abdominal distension may also be associated with infection by *Lambia intestinalis*. The degree of wasting never reaches that of severe coeliac disease, and examination of the stools for *Lambia* cysts will distinguish the two conditions. There is also a group of children who exhibit steatorrhoea as an accompaniment to severe and prolonged infection, and in such the character of the stools and the degree of wasting may simulate coeliac disease. As a rule, however, a reduction in dietary fat quickly checks the steatorrhoea, and when once the chronic infective stage is passed the fat in the diet can be restored within a few weeks.

Lastly, the clinical state that results from fibrocystic disease of the pancreas mimics very closely that of coeliac disease, for steatorrhoea, severe malnutrition, and abdominal distension are common to both, yet the two conditions are in fact unrelated, and on clinical grounds alone it is usually possible to distinguish them.

The several conditions enumerated above share in common the symptoms of fatty stools, wasting, and abdominal distension, and it has become fashionable in paediatric parlance and literature to speak of young children who exhibit them as suffering from the "coeliac syndrome". This implies that coeliac disease is not a separate clinical entity but a state compounded of a group of symptoms which can be broken down into various causes. It can, however, be contended that by clinical investigation and laboratory aids it is possible to separate the other causes and to leave a residue of children whose illness conforms to the original clinical concept of coeliac disease. Although it must be confessed that coeliac disease remains an idiopathic condition, the retention of the name is advantageous if only to avoid confusion with other causes of steatorrhoea in young children—a confusion which the term "coeliac syndrome" encourages.

## Fibrocystic Disease of the Pancreas

This is the illness most easily confounded with coeliac disease, and the two conditions may therefore be contrasted. The identification of pancreatic fibrosis may be said to date from 1938, when Andersen reviewed the literature and collected a group of 49 cases. Since then the disease has become widely recognized and the literature on the subject has rapidly expanded.

In contrast to coeliac disease, pancreatic fibrosis has a definite tendency to affect more than one member of a family, indeed, a familial incidence occurs in roughly a quarter of the cases. It is rare for coeliac disease to do this, and for more than one child of a family to be affected must be regarded as probably fortuitous. The age of onset is notably different, for, while coeliac children develop normally for several months up to a year or more after birth, those with pancreatic fibrosis present symptoms from birth, and the underlying pathological process probably originates in most cases during intrauterine life. The effect of the disease is to reduce, often to vanishing point, the external secretion of the pancreas, and when this occurs before birth the meconium may be of such stiff consistency as to give rise to symptoms of intestinal obstruction within a few days of birth, often with fatal results. The name "meconium ileus" aptly describes this state of affairs. Among the 49 cases of pancreatic fibrosis collected by Andersen there were two instances of meconium ileus, the first having been described by Landsteiner in 1905. In addition, two infants showed intestinal atresia.

Another point of contrast lies in the state of the appetite. Coeliac children have a notoriously fickle appetite, but infants with pancreatic fibrosis have a good, even voracious appetite, although in spite of this they persistently fail to thrive, and by the time they reach the age of 1 year may be several pounds below their expected weight.

Malnutrition and abdominal distension are notable features in the pancreatic group, becoming apparent within a few months of birth, while the stools tend to be large, loose, pale, and decidedly offensive. These symptoms also characterize coeliac disease, and it can be readily understood that if a child with pancreatic fibrosis is not seen until the age of 1 year or more these features may at first lead to confusion with coeliac disease, although a careful history should suggest the correct diagnosis. A small point, but of some help to those with experience of both conditions, is that the odour of the stools in pancreatic fibrosis is even more repellent than that of the coeliac stool, probably by virtue of the fact that while both stools contain an excess of fat and starch the pancreatic stool also contains unabsorbed and decomposed dietary protein.

In both conditions a barium meal shows a loss of the normal feathery pattern of the small intestine, which is replaced by a clumping of the barium into separate masses of varying size. The rate of passage of the barium to the caecum tends to be accelerated.

## Pulmonary Complications

There is, however, a further point of contrast between coeliac disease and pancreatic fibrosis, for in the latter condition sooner or later, and often within a few months of birth, chronic pulmonary suppuration develops. There may be a history of one or more attacks of bronchopneumonia in infancy from which recovery has been all too tardy; in others the lung infection develops without a definite history of acute illness, but eventually the clinical picture is that of bronchiectasis, with production of purulent sputum, breathlessness, cyanosis, and perhaps finger-clubbing. Once this state has developed, the previously

\*Read in opening a discussion in the Section of Radiology at the Annual Meeting of the British Medical Association, Cambridge, 1948.

good appetite is likely to be lost, treatment of the lung condition is thoroughly unsatisfactory, and the state of the child steadily deteriorates until in a matter of months or a few years the disease in the chest kills the patient

Various reasons have been put forward to account for the proclivity to pulmonary complications. These infants have a flat vitamin-A absorption curve, and lack of this vitamin has been supposed to contribute to the liability to respiratory infection but coeliac children also have a flat vitamin-A absorption curve (May *et al.*, 1942), which in both conditions is ascribed to failure to absorb fat, and yet gross lung disease is not particularly encountered in the coeliac child. It is more probable that the respiratory troubles of the child with pancreatic fibrosis are in the main due to congenital cystic disease of the lungs, the lesions in lung and pancreas being due to a common foetal pathology

Respiratory infection is so prominent in children with pancreatic fibrosis that it seems probable that, prior to Andersen's article in 1938, children with this condition were regarded as suffering primarily from bronchiectasis or chronic lung infection rather than that they were confused with cases of coeliac disease

### Laboratory Findings

In addition to the clinical distinction between the two diseases, laboratory investigation also reveals decisive differences. Thus Farber *et al.* (1943), in 150 analyses of the pancreatic enzymes obtained from the duodenal contents of infants and children, showed that trypsin, lipase, and amylase were produced in normal amounts by coeliac children but were either absent or very much reduced in children with pancreatic fibrosis. Herein lies an important method of differentiation. As regards lipase, the technical difficulties in its estimation and the wide range of values obtained from control cases prevent the assay of this enzyme from being used for the routine confirmation of the diagnosis of pancreatic fibrosis. As to amylase, its very low production by infants under 6 months of age and the fact that amylase from the saliva may be recovered from the duodenum, particularly when gastric hypochlorhydria is present as often happens in coeliac children, make the evaluation of this enzyme unsuitable as a diagnostic aid. The presence of trypsin is however, easy to estimate by its digestive effect on a standard solution of gelatin and at the present time lack of trypsin in the duodenal juice is the criterion upon which a diagnosis of pancreatic fibrosis is acceptable.

Further evidence of failure to digest protein has been furnished by West *et al.* (1946), who showed that there is a normal blood amino-nitrogen curve following ingestion of such proteins as casein and gelatin. Infants with coeliac disease have a normal curve, those with pancreatic fibrosis have a flat curve after ingestion of either casein or gelatin, although the curve is normal after ingestion of casein hydrolysate, and a combination of pancreatin with casein tends to restore the curve towards normal.

The advantage of pancreatin in the treatment of pancreatic fibrosis was also pointed out by Shohl *et al.* (1943), who showed that this preparation tended to lower the nitrogen content of the stools but considered that it did not benefit fat digestion, although Andersen (1945) contended that it reduced both the total faecal excretion and the amount of faecal fat. She regards an optimum diet for children with this disorder to be one in which protein provides 25% of the calories, the fat content is low, and carbohydrate is given mainly as sugar, with small amounts of starch for older children. There is clearly an advantage in making casein hydrolysate a regular feature of the diet

and even in infancy not less than 60 gr (4 g) of pancreatin (enteric-coated) should be given daily with the meals.

Apart from dietetic management, treatment of pancreatic fibrosis has also to contend with infection in the lungs. This complication affects the prognosis so adversely that every attempt must be made to prevent its occurrence. Good hygienic surroundings and the avoidance so far as possible of droplet infections are obvious measures. It is as yet too soon to assess the prophylactic value of oral penicillin.

### Clinical Manifestations of Coeliac Disease

These are too well known to require reiteration, but a review will be given of some commonly held views in the light of recent investigations. Of the many excellent and authoritative clinical descriptions tribute must be paid to Gee's original article in 1888 on the coeliac affection, to Still's Lumleian Lectures delivered in 1918, and to Parsons's Rachford Memorial Lectures of 1932. Still drew attention to the small size of the liver as a common characteristic, and although later authors seldom refer to this feature it is a clinical detail of some diagnostic value owing to its constancy.

Parsons completely summarized our knowledge of coeliac disease up to 1932, and at that date the condition was generally regarded as a well-defined entity. The onset is usually between 6 and 18 months of age (see Chart), and

Chart showing age of onset in 87 cases of coeliac disease

the clinical picture is characterized by a group of symptoms the most prominent of which consist of severe wasting, a striking degree of abdominal distension, and the passage of large, unformed, pale offensive motions containing an excessive quantity of fat, mostly in the form of fatty acids and soaps.

Although it has for long been generally appreciated that starchy foods are badly borne, and indeed Howland in 1921 regarded a failure to manage carbohydrate as the primary trouble, the view that failure to absorb the products of digestion of fat is the principal fault in coeliac disease, other digestive and absorptive errors being of a secondary nature, has for many years had popular support. This view has largely dictated the lines of treatment, of which the first principle has been a severe curtailment of dietary fat. The effect of this has been to diminish the amount of fat excreted in the stools, and the maintenance of a low faecal-fat excretion has been regarded as advantageous. A reduction of starchy food has also proved to be necessary in order to avoid troublesome diarrhoea.

Consequently the dietetic management of coeliac disease has consisted of giving in the first place an almost purely protein diet, followed by the cautious addition of starch—a stage usually difficult to establish because of the liability to diarrhoea. The final stage has been the reintroduction of fat. These stages have always taken months, and sometimes even years, to attain. Throughout treatment the addition of vitamin concentrates has largely abolished the development of deficiency complications, which were at one time a common feature of coeliac disease.

### Aetiology

The view that coeliac disease itself, apart from its complications, might be in part a deficiency disorder, has been put forward by May *et al* (1942), who claimed that the intramuscular administration of crude liver and vitamin B restored the vitamin-A curve to normal and improved the glucose-absorption curve. These substances were much less effective by mouth, suggesting that their absorption from the intestine was defective. In this country Paterson *et al* (1944) reported favourably on this method of treatment, but others have been less successful, and as daily intramuscular injections are undoubtedly irksome to the children this form of therapy has not gained popularity.

There are certain points in the history of coeliac disease which should be borne in mind when seeking for an adequate aetiology. For example, it has already been pointed out that in the early months of life, before the illness develops, the infants thrive satisfactorily on a diet of either breast milk or cows' milk, and clearly at that stage the digestion and absorption of the various elements of milk present no difficulty. As there is no starch in milk, amylase is not required by the young infant, but both trypsin and lipase must be present. If failure to utilize fat is eventually to appear, there is no hint of this in the early months, nor does the history of the feeding of coeliac children in early infancy depart in any respect from the routine methods applied to infants in general.

The age of onset of coeliac disease in most cases coincides roughly with the stage when the diet is expanding from milk to mixed feeding. This means the introduction into the diet of new types of protein and fresh forms of animal and vegetable fat, but the greatest change at this age is the addition to the diet of starch in rapidly increasing amount. In this connexion it is of interest that analyses of duodenal juice (Farber *et al* 1943, Andersen, 1945) have shown that while trypsin and lipase are present from birth the amount of amylase is negligible in the first three months, but then gradually rises to reach a maximum at about the age of 3 years.

### Fat Intake

The view that coeliac children fail to absorb fat is based upon the excretion of excessive amounts of fat in the stools, and the flat vitamin-A absorption curve has been regarded as corroborative evidence of this view. It is, however, open to argument whether the results of faecal-fat analyses justify a sharp reduction of the dietary fat. Fat balances show that in health at least 90 to 95% of dietary fat is absorbed, and at the same time stool analyses in healthy infants and children show that fat accounts for from one-quarter to one-third of the dried stool. Even if the amount of faecal fat were doubled (as often occurs in coeliac disease) it would still be possible for at least three-quarters of the ingested fat to be absorbed, therefore, unless it can be shown that the steatorrhoea of the coeliac child is harmful and must at all costs be reduced, it would seem illogical to deny them fat in their diet.

The striking degree of abdominal distension in the coeliac child can hardly be due to the high faecal-fat excretion, for

in young infants fed on a diet containing more fat than they can tolerate gross abdominal distension is not a clinical feature, nor does it accompany the steatorrhoea associated with liver damage in older children. The distension may be due to some extent to loss of muscle tone, but in the main results from excessive fermentation of carbohydrate, and the diarrhoea to which these children are so notoriously prone is due to carbohydrate fermentation rather than to steatorrhoea.

For the above reasons, while accepting the fact that coeliac children pass an excessive amount of fat in their stools, the view that fat in their diet should be severely reduced is difficult to maintain, indeed, the evidence would suggest that attention ought to be directed primarily towards their difficulty with starches. This attitude has been developed by Andersen (1947), who considers that the steatorrhoea of coeliac children is not part of the basic process but that the long-recognized clinical intolerance towards starch is of primary importance. She contends that the production of pancreatic amylase is deficient, that feeding of starch leads to excessive excretion of faecal starch in extracellular form, and that a good clinical response follows the elimination of starch from the diet, which should otherwise contain a normal proportion of fat and a relatively high amount of protein. In passing, it is of interest to note that Gee, in his original description, recommended giving good fresh butter and even advised a trial of cream.

The whole question of fat absorption in coeliac children has become further complicated by the new views on the physiology of fat absorption put forward by Frazer (1943). He regards as untenable the older view that all fat requires breaking down to fatty acids and glycerol before being absorbed into the intestinal cell, where it is resynthesized before passing into the lacteal system. He has demonstrated that a proportion of the dietary fat is finely emulsified in the upper intestine and is absorbed as fat particles into the lacteals, then passing via the thoracic duct to the various fat depots in the body, the proportion of dietary fat which escapes this process is digested to fatty acids and glycerol, these substances being absorbed into the portal system and passing to the liver.

If Frazer's views are accepted, it remains to determine which system of fat absorption is at fault in coeliac children or whether both are defective. In any case, for the reasons given above, the estimation of total faecal fat and its division into split and unsplit proportions loses much of its significance as a guide to treatment, although it may retain some diagnostic importance. Clearly a knowledge of the amount of dietary fat which a coeliac child absorbs is of far greater value than estimations merely of faecal-fat excretion, but for this information fat balances must be carried out. As a guide to treatment these should replace the customary estimations of faecal fat.

Mention must also be made of the flat oral-glucose absorption curve which is so characteristic of coeliac disease. Intravenous glucose given to coeliac children is metabolized at a normal rate and the flat oral curve is generally taken to indicate difficulty in the absorption of glucose from the intestine. This view has been attacked by Emery (1947). He has shown that, while in coeliac children the fall in blood sugar induced by insulin follows the usual pattern, the subsequent return to a normal level fails to materialize, although it can be restored by giving glucose orally. The effect of adrenaline on the blood-sugar level gives a smaller and slower response in coeliac children than in normal controls, although if glucose is given by mouth at the same time as the injection of adrenaline a normal response ensues. For these reasons he argues that coeliac children absorb glucose normally and utilize it

normally, he explains the flat oral-glucose curve as being due to lack of available glycogen in the body, with the result that oral glucose is utilized by the liver as fast as it enters the portal system

### Summary

It is contended that coeliac disease maintains to day its position as a clinical entity, and can be distinguished from fibrocystic disease of the pancreas and from the other causes of steatorrhoea in childhood. To group all these conditions under the term "coeliac syndrome" is confusing. The facts regarding excessive faecal-fat excretion and the flat oral-glucose absorption curve in coeliac children are not disputed, but their significance requires reconsideration.

The view that coeliac disease is due to a defect in the absorption mechanism of the intestine does not as yet rest on a sure foundation. It may still remain to identify the varying clinical conditions that result from a failure to produce any one of the several enzymes required for complete digestion.

## A STUDY OF BREAST-FEEDING IN A MINING TOWN

BY

ENID L. HUGHES, MB, BS, MSc, DCH

Assistant County School Medical Officer Northumberland

This work is a study of the incidence of breast-feeding during the five war years, 1941–5, in Newbiggin-by-the-Sea, a small town on the coast of Northumberland, and continues a similar study of the babies born in 1940 (Hughes, 1942).

Many previous surveys of this problem have been weakened by the fact that they cover only part of the community. This is an attempt to study a whole community. Newbiggin lends itself to such an inquiry, as there is a very large attendance at the infant welfare clinic, so that a picture has been obtained of nearly 90% of the infant population. There was no social distinction at the welfare clinic. The curate's wife and the doctor's daughter brought their babies as did the miners' wives and local "ne'er-do-weels".

### The Community Studied

Newbiggin-by-the-Sea—once a fishing village—is now a small town with a population of just over 9,000, mostly concerned in mining. The war did not hit the village very hard. There was frequent passage of enemy planes, and one stick of bombs was dropped (known locally as "Werblitz"). The population was temporarily swollen in 1943–4 by private evacuees from the South and in 1942 the call-up began to affect the fathers of the infant population. In 1941 62% of the fathers of the babies here recorded were miners and 11% were in the Forces, in 1942, 49% were

miners and 25% were in the Forces, and in 1945 the figures were 46% miners and 35% in the Forces.

There was no real poverty throughout the period studied, but the larger families were perhaps less well catered for than in other places, since there are no school meals in Newbiggin. The miners' canteen was not well patronized, so that in a large family the mother's nutrition was likely to suffer.

An increase in the number of hospital deliveries is very evident over these five years. In 1940 (Hughes, 1942) midwives delivered 77% of the babies, 11.5% were doctors' cases, and 11.5% were born in nursing-homes or hospitals. By 1943 the figures were 71% midwives' cases and 25% hospital deliveries. In 1945 62% were midwives' cases, 5% doctors' cases, and 32% hospital deliveries. This change was mainly due to the difficulty of getting help in the home. Even so, it will be seen that the great majority of deliveries were by midwives.

### Present Investigation

The babies here studied are those born of Newbiggin parents in 1941–5 inclusive and continuing to live there till at least 6 months old. (This excludes the babies dying before the age of 6 months, evacuee babies born elsewhere, and babies whose mothers came to Newbiggin for the birth and moved soon afterwards.) Of the babies thus defined, 89.4% attended the clinic regularly enough over these five years for details to be recorded of their dates of weaning. The actual numbers are given in Table I. (The drop in 1943 is due to my illness and absence from work for several months.) The figures for 1940, previously published, are included for comparison.

TABLE I—Proportion of the Infant Population Studied in each Year

Year	No Born and Lived 6 Months	No Included in Records
1940	117	112 (95%)
1941	114	105 (92%)
1942	137	124 (91%)
1943	116	98 (85%)
1944	146	131 (90%)
1945	100	90 (90%)

The time of weaning is recorded in Table II, including also the 1940 figures. Figures of those completely breast-fed at 3 months are included. Comparison with the percentage weaned by 3 months will give the percentage who had their babies partly on the breast at this age.

TABLE II—The Incidence of Weaning

Year	No Recorded	Percentage Weaned by				Percentage Completely Breast-fed at 3 Months
		2 Weeks	1 Month	3 Months	6 Months	
1940	112	31		57		32
1941	105	32	40	67	81	30
1942	124	36	45	65	83	25
1943	98	25	34	47	80	30
1944	131	23	37	57	83	30
1945	90	27	40	59	83	24
1941–5	548	29	39.5	59	82	29

This is a very high and maintained proportion of early weanings, and exceeds any other published figures I have seen.

Among those weaned by 2 weeks there is the same proportion of first babies (47%) as among the whole number recorded. It is usually stated that babies delivered by midwives are breast-fed more successfully than babies born in hospital. Here, however, 32% of all the babies delivered by midwives and 20% of those delivered in hospital were weaned by 2 weeks.

## Reasons for Very Early Weaning

An attempt was made to assess the reasons for weaning before 2 weeks (162 cases, 29%). The mothers were not pressed for an explanation if they seemed unwilling, nor was there time for a detailed history of the failure of lactation. In some cases undoubtedly the full story was not given by the mother, as reference to her midwife afterwards showed. Table III gives the reasons as stated by the mothers. Some points about this table are of interest.

TABLE III—Reasons for Early Weaning

Illegitimacy	12
Mother's serious illness	12
Child's illness or abnormality	3
Mastitis or trouble with nipples	12
Fear of recurrence of illness (usually mastitis)	7
Difficulties with baby at breast	13
Worry	4
Mothers' refusal to breast feed	7
Domestic demands	13
Reason difficult to establish	79
Total	162

Of the 12 who weaned on account of mastitis or trouble with the nipples, eight were primigravidae. This seems important, as the fear of a repeated mastitis is a potent discouragement in attempting to feed a second child. When the baby had difficulties at the breast—e.g., sleepiness or fighting with the breast—breast-feeding was often given up after only three or four days of trial. Of the women who said they did not want to breast-feed four were primigravidae. Reasons given were, "Want to get about," "Too embarrassed," "Too old at 46." However, the most striking thing is that for nearly half the women who weaned by 2 weeks no reason was satisfactorily established.

It was felt that the views of the "people on the job"—i.e., the midwives—were important in studying this problem. There are three midwives working in Newbiggin. Two are employed by one nursing association, towards which the colliery subscribes. The elder of these midwives has been working for 22 years in Newbiggin and the patients "are able to tell her anything." She and her young assistant are quite sure that a large number of young mothers do not wish to breast-feed because it ties them, prevents them going to dances and the pictures, and may spoil their clothes. She thinks this began when the dried milk became cheap. She knows many cases where the young mother is quite open in her determination before the confinement not to feed her baby. In her experience trying to overrule this results only in a breast abscess, as the mother will resort to a bottle when the nurse is not there, and if hospital-confined will wean immediately on coming out of hospital. "They know breast-feeding is the right thing but they won't be tied."

The third midwife is employed by another nursing association and has perhaps a slightly different clientele from the other two. She was a highly trained hospital sister before coming on the district, and has been working here seven years. Although she thinks there is a large element of truth in the views just set out, she sees a social background to much of this early weaning. In her opinion early weaning is much more likely where the mother is living with her in-laws. In such cases there is little chance of privacy, the mother is embarrassed at exposing her breast before her mother-in-law (and possibly other members of the family). The sense of outraged modesty affects the baby, who begins to "winge" (whimper), and in a few minutes the mother-in-law will say, "That's not feeding the bairn, you'll want to get summat that'll satisfy it. Give it summat in a bottle."

She also points out that in these colliery houses where several men are working shifts there is nearly always a man in bed trying to sleep. The baby must be kept quiet. The baby, in a pram, is usually in the living-room, as these

houses generally open on to the pavement and have very small backyards. An older woman may encourage the mother to bottle-feed, as then there is "always a way of hushing the child if the mother is out." This midwife states also that it is "quite impossible" for fisherwives to feed their babies, as the custom is for them to start work on the nets directly they are out of bed.

On this question of the fisherwives, I am indebted to Dr. Stephenson, who has been in general practice in Newbiggin for many years, for the following information: "I fear that some of the young fisherwomen now wean early, but their mothers and grandmothers did not wean until 12 months. So far as I can remember, and from questions put to fisherwomen, these amazingly hard-working women brought up all their children on the breast. They baited at least one line a day (700 hooks), cooked the family meals, produced the children, fed them on the breast, helped to pull the boats up when the men came back with the fish about 11 a.m., helped to carry the fish up, baked the bread, did the washing and ironing, cleaned the house, bathed the children, went to bed about 9 p.m. and got up again about 4 a.m. to get the men ready for the morning's fishing. In the palmy days before the mine, when Newbiggin was a holiday resort, some of the fisherwomen even acted as wet-nurses for the delicate children of visitors."

## Comparison with Other Parts of the County

How does Newbiggin compare with other colliery districts? Are these early weanings as common in the rural areas of Northumberland? In order to throw light on these questions a survey was made of the health visitors' records in six areas in the county, covering all the children born in 1944 and 1945 (wherever they were born) and now living—i.e., aged 3 and 4 years—in these areas (620 cases). These records are comparable with each other, but not strictly comparable with the Newbiggin cases, which related to all babies who lived to 6 months.

The information sought was whether the baby was weaned before or after the age of 1 month. It was found, however, that in most districts only 70 to 80% of the cards could give this information, and it was not considered that this was an accurate picture. In one district, however—Allendale, a rural hilly area—96% of the cards had this information, and in one mining area—Shiremoor—with a population very similar to that of Newbiggin, 83% of the cards gave the desired information. These figures are given in Table IV.

TABLE IV—Comparison of Rural and Mining Areas (Health Visitors' Records) Northumberland

District	Total No. Born 1944-5 now Living in District	No. Weaned Before 1 Month	No. Weaned After 1 Month	No. of Incomplete Records
Allendale (rural)	92	20 (22%)	68 (74%)	4 (4%)
Shiremoor (mining)	138	51 (37%)	64 (46%)	24 (17%)

It is clear that these numbers of cases are too few to carry much weight, but it is highly suggestive that Shiremoor, with a mining population very like Newbiggin, has at least as great a proportion of early weanings, and that this is in great contrast to a rural district. It is interesting that in the Allendale district the health visitor reports that most young couples manage to have a place of their own and to avoid living with "in-laws." Not only does this mean privacy but it means that there is no older woman to keep house and give a bottle if the mother goes out. It is obvious that there is no statistical evidence here either to support or to refute this as a predisposing factor in early weaning, and that many other factors may be involved.

### Discussion

The large numbers of early weanings in Newbiggin contrast forcibly with other investigations on the subject. The Ministry of Health Report (1944) estimates that 95% of babies born in the district are wholly breast-fed when the midwife leaves. Finlay, quoted by Spence (1938), in a home-visit investigation of 3000 cases in Edinburgh found that 87% of the babies were breast-fed at the 10th to 14th day. Robinson (1939), analysing 439 Liverpool welfare cases found that 86% were breast-fed at 2 weeks.

A report to the British Paediatric Association, 1942, on breast-feeding in Birmingham (with special reference to female labour) shows similar figures—e.g., in 1937, in 13% of 4,378 cases the children were not breast-fed at the first visit. Similar figures occur in 1941 and 1942. These investigations, however, do not cover whole populations but deal with selected groups.

Why, then the Newbiggin figures? In the main work described here the data were collected by me from the mothers at the infant welfare centre. Nearly all the dates of weaning were noted within a few weeks of the occurrence and in the many cases of weaning by 2 weeks it was noted at the first attendance, usually at 3 to 4 weeks of age. This was done simply as an easy way of getting the facts as soon as possible. Later, however, I began to wonder if it were not a rather important point. In asking several mothers about the feeding of previous children two or three years back I was able to check their accuracy with the week-to-week records kept at the time, and the replies very often diverged from the recorded facts—i.e., the child would be said to be weaned at 3 months when it was actually 5 weeks. Indeed, my own figures for 1943 (see Table II) are open to this doubt, since illness prevented me from collecting some of the data as promptly as usual.

This experience raises a doubt about the accuracy of dates of weaning recorded in large-scale investigations relating to a year or two back. So long as breast-feeding is held to have the moral value referred to in the Ministry of Health Report, so long surely will mothers tend to give an "acceptable" reply when asked about the weaning of their children. Indeed, this moral atmosphere probably colours all replies on the subject. My experience of analysing health visitors' records suggests, too, that the first visit may be at a very variable time after the birth.

Attention has been directed by the work of Robinson (1943) and of Waller (1946) to the physiological mechanisms inherent in lactation. No attempt has been made in this work to assess the factor of overloading (Waller, 1943, 1946) in the early weaning, and it may exist in cases unsuspected even by experienced midwives.

Undoubtedly there seems here to be a large social element. Custom or fashion, overcrowding, lack of privacy and the presence of an older woman who will quite literally "hold the baby" are all possible contributory causes.

Do colliery districts in other parts of England present similar problems? Is overcrowding a factor elsewhere? Is the desire "not to be tied" an unexpressed but important cause? And is there support in other counties for the suggested difference here between mining and rural areas?

### Summary

The incidence of breast-feeding has been studied over five years in a mining town in Northumberland (548 cases forming 99.4% of the babies born and living there 6 months). It was found that 29% of these babies were weaned by 2 weeks and 70% by 1 month of age. These figures are supported by health visitors' records for 1944-5 in another mining area and contrasted with a rural area. Further investigation of these differences seems advisable.

The cause of the large number of early weanings is discussed.

I wish to thank Dr. Stephenson, of Newbiggin, for the information quoted, and the health visitors and midwives for their ready help and co-operation. I also thank Dr. Jameson, county maternity and child welfare officer, for the interest she has shown, and Dr. Tilley, county medical officer of health, for permission to publish this work.

## SURGICAL SIGNIFICANCE OF AORTIC DISSECTING ANEURYSMS

### REPORT OF THREE PERSONAL CASES WITH TWO CORRECT ANTE-MORTEM DIAGNOSES

BY

D. P. VAN MEURS, FRCS

Surgeon, County Hospital, Farnborough

The symptoms caused by aortic dissecting aneurysms occasionally suggest surgical abdominal disease. Although about half the sufferers from this condition succumb in less than 12 hours, it is not uncommon for death to be postponed for over a week, and recovery for a varying period, though infrequent, can occur. Hence a correct diagnosis, or, at the worst, recognition of the condition at operation, would be of great assistance from the point of view chiefly of prognosis and also in the event of any reasonably successful form of treatment being devised.

The condition has rarely been diagnosed ante mortem. Shennan (1934) could find records of only six such cases, although about eight others have been described since. It is possible that more frequent correct diagnoses could be made were the condition borne in mind, and it is felt that a brief summary of the pathology, symptoms, and physical signs, together with the details of three personal cases, would be of value.

### Pathology, Symptoms, and Physical Signs

**Pathology.**—The condition probably arises from a tear in a diseased medial coat (Morani, 1910), the immediate exciting factor being a temporary rise in blood pressure. Less commonly an atheromatous plaque may determine the site of rupture. Syphilis is rarely associated. The split is most commonly situated in the ascending aorta and occurs less often as the vessel is traced downwards. The dissection is rarely localized and saccular, but usually spreads for a variable distance downwards, and has been known to reach the popliteal arteries (Tessier, 1842). Proximal dissection, though usually slight, may be extensive. Death is usually caused by rupture, most commonly (70%) into the pericardium, but also into the mediastinum, pleural space, peritoneal cavity, or retroperitoneal tissues. The aneurysm may rupture back into the lumen of the vessel, although this course does not necessarily prevent rupture to the exterior. There is little relation between the site of the tear, the length of the dissection, and the time of survival.

**Symptoms and Signs.**—The onset is rapid, and is often associated with physical or emotional strain. There may be a feeling of something suddenly giving way in the thorax, with a sensation of choking. Sudden pain may be felt in the thorax, abdomen, or back and it may be substernal, epigastric, or, characteristically, girdle in type. The pain is frequently intermittent, resembling colic, and may be accompanied by nausea or faintness. These attacks of pain

may last for a few hours, and relief is usually gradual. Intervals between attacks may be of hours, days, or even weeks. Attacks of pain probably coincide with extension of the dissection or external rupture. Dysphagia may be an early symptom, but vomiting, haemoptysis, and haemorrhage from the bowel are not common. The onset and subsequent attacks of pain are usually accompanied by a varying degree of collapse.

Other symptoms may be produced by involvement of branches of the aorta or pressure by the aneurysm on surrounding structures. Hence cerebral symptoms, disorders of sensation, gastrointestinal disorders, weakness, or paralysis may all occur (Moosberger, 1924). The pulse may show some irregularity and there may be a difference between the two sides. Absence or irregularity of the pulse on one side may be of temporary duration only. On the whole, little information is to be got from this examination. Similarly the heart rarely gives helpful physical signs. Left ventricular hypertrophy is usually but not invariably present.

In view of the severity of the symptoms, the abdominal signs are not striking. Slight tenderness and guarding, with perhaps some distension, may suggest abdominal disease. If the abdominal aorta is involved then the aneurysm may be palpable, abnormal pulsation may be present, or the clot arising after rupture may give a detectable mass.

**Diagnosis**—The picture is so variable that there are only a few common points which could be labelled as diagnostic criteria: (1) A sudden onset is invariable and usually occurs during conditions which could cause a temporary rise in the systolic blood pressure, (2) the pain is often intermittent, disappearing gradually, (3) abdominal pains are usually epigastric, radiating through to the back, or of the girdle type, (4) symptoms and signs may shift downwards in recurrent attacks, (5) there may be a palpable aneurysm or clot or abnormal pulsation, (6) there may be associated neurological or cerebral symptoms, and (7) thoracic symptoms may be anomalous—e.g., anginal with no history of previous attacks, or resembling those of a coronary thrombosis with a persistently high blood pressure.

### Case 1

A man aged 69 was admitted on Feb 20, 1944. During a fit of coughing on the day before admission he had a sudden attack of pain in the lower abdomen, left groin, and back, associated with nausea, faintness and numbness of the left leg. A left inguinal hernia, previously reducible, came down and he could not reduce it. The pain was severe at its onset but had since eased considerably. He had not vomited.

The patient was a well built man and appeared moderately shocked. The temperature was 97° F (36.1° C), pulse 85, respirations 25. The heart was enlarged to the left. The blood pressure was 110/60. The hernia was irreducible but did not appear to be the cause of his symptoms. The upper abdominal aorta was markedly enlarged, and there was slight tenderness to the left of the umbilicus. No definite mass could be felt. No neurological signs were elicited. Leaking dissecting aneurysm of the abdominal aorta was diagnosed. His general condition slowly deteriorated. Three days later his scrotum was discoloured and a vague mass could be felt in the left half of the abdomen extending into the left loin. He died next day.

Post-mortem examination disclosed a dissecting aneurysm involving the whole of the abdominal aorta, with rupture into the peritoneum and hernial sac and into the retroperitoneal tissues. The coronary arteries and aorta showed marked atheroma and the heart left ventricular hypertrophy.

### Case 2

A woman aged 48 was admitted on Nov 9, 1945. She had a sudden onset of pain two days before admission while putting on her coat. It was in the left subcostal region and radiated

through to the back, and was stabbing in character. Next day she vomited several times.

The patient was a well built woman, rather collapsed. The temperature was 100° F (37.8° C), pulse 80, respirations 20. The heart was enlarged to the left. The blood pressure was 145/100 and later increased to 244/100. There was tenderness and guarding in the left subcostal region. Albumin was present in the urine. No definite diagnosis was made. The pain gradually diminished but three days after admission it recurred over the left chest posteriorly, and three days later this spread to the left lumbar region. The blood pressure was now 190/120. Her condition began to deteriorate, and nine days after admission she was semicomatose. She could just be roused, and complained only of dimness of vision. A pericardial friction rub now became audible and persisted for ten days, while her general condition did not alter much. Radio-graphs of her chest first showed any change 17 days after admission when both bases were obscured. Thirty days after admission she became pyrexial and showed signs of congestive cardiac failure, and she died six days later. Numerous investigations were done, with no results worth reporting.

Post-mortem examination showed a fibrinous pericarditis with a hypertrophied heart. The aorta was grossly atheromatous and a dissecting aneurysm started in the transverse aorta and re-entered the vessel 8 cm above the bifurcation. At the latter point there was a large thrombus in the inferior vena cava. The lungs were oedematous and the liver showed nutmeg changes.

### Case 3

A man aged 65 was admitted on Jan 31, 1946. Two hours before admission, while hurrying to work, he had a sudden onset of severe pain across the upper abdomen, and collapsed in the street. The pain persisted, with occasional acute exacerbations, and radiated through to the back. He had nausea but did not vomit. He was a well built man showing signs of collapse. The temperature was 97° F (36.1° C), pulse 66, respirations 22. The lungs were normal. The heart was enlarged to the left. The blood pressure was 200/140. There was tenderness in the epigastrium and left hypochondrium with slight guarding. His symptoms diminished over the next two days but then he began to get further severe attacks mostly at night lasting about two hours each. These were felt mainly in the epigastrium and radiated through to the back, and made him very restless. By the fifth day after admission his abdomen became rather distended, and as his bowels had not been opened, he was given two enemata. No result was obtained and a diagnosis of large-bowel obstruction was considered. However, a further enema produced a good result. The next day the case was thoroughly reviewed. The maximum abdominal tenderness was just to the left of the umbilicus and for the first time abnormal pulsation could be felt at this point. The blood pressure was 200/125 in both arms and there were no chest or neurological signs. His general condition was good.

The diagnosis of dissecting aortic aneurysm was then made on the following grounds: (1) sudden onset of pain during exertion, (2) site of the pain and its radiation through to the back, (3) signs of collapse on admission, (4) pulse rate (66) and blood pressure (200/140) excluding a coronary lesion, (5) the difficulty in diagnosing any abdominal disease, (6) the detection of abnormal pulsation to the left of the umbilicus, (7) the shifting downwards of the tenderness, and (8) the intermittency of the attacks of pain and their gradual disappearance. The patient later continued to have severe attacks of pain, partly controlled by morphine, and he died suddenly during an attack nine days after admission.

Post-mortem examination showed a dissecting aneurysm starting in a transverse slit 2 cm long in the posterior surface of the upper part of the descending thoracic aorta and extending to the bifurcation. There was moderate atheroma of the aorta and coronary arteries. A large clot of blood (1 500 g) filled the posterior mediastinum and extended behind the left pleura.

### Comments

In Cases 1 and 3 the diagnosis could be made without much difficulty. The symptoms remained such that had a correct diagnosis not been made persistent search

for a surgical abdominal lesion might have resulted in a laparotomy. As it was, the prognosis given to the patients' relatives was rather more than guarded. Case 2 was obviously not a surgical case a week after admission. Being wise after the event, it seems strange that this case was not diagnosed, and reference to the case histories of other patients admitted to medical wards with the same condition suggests that correct diagnosis was not impossible.

### Summary

Patients with aortic dissecting aneurysms are sometimes admitted into surgical wards.

A brief summary is given of the pathology, symptoms, and signs of this condition.

Three case histories are given, in two of which a correct antemortem diagnosis was made.

It is suggested that a correct diagnosis could be made more often.

Free reference has been made to the excellent symposium on the subject by Shennan (1934).

## LIQUOR PICIS CARBONIS (B.P.)

### A CARCINOGENIC AGENT

BY

I BERENBLUM, M.D., M.Sc.

(From the Oxford University Research Centre of the British Empire Cancer Campaign, Sir William Dunn School of Pathology, University of Oxford)

From our knowledge of occupational tumours in man and from results of animal experiments, coal-tar must be considered among the most potent carcinogens for skin epithelium. Possible dangers arising from its incorporation in therapeutic preparations for dermatological use cannot, therefore, be ignored.

In the early studies of experimental carcinogenesis several investigators (Sternberg, 1923, Lipschutz, 1924, Berghoff, 1928) examined a number of tar-containing therapeutic preparations in use on the Continent and found these to be carcinogenic for mouse's skin. The preparations tested were carboneol (a solution of coal-tar in carbon tetrachloride), lithanthrol (a solution in ethyl chloride and ethanol), and carboterpin (a solution in a mixture of terpenes).

The corresponding preparation in use in this country is liquor picis carbonis (B.P.), which consists of a 20% solution of coal-tar in ethanol. In view of its wide use in dermatological practice an experimental investigation of its carcinogenic properties was thought desirable. (This was suggested by Dr J. R. Squire, of the M.R.C. Industrial Medicine Research Unit, Birmingham Accident Hospital, and by Dr E. H. Capel, late medical officer to Joseph Lucas Ltd., Birmingham.)

### Carcinogenicity Tests on Mouse's Skin

Twelve white mice were painted twice weekly for 41 weeks with undiluted liquor picis carbonis (B.P.) on a small area of skin in the interscapular region. Papillomas appeared in the treated areas of skin in seven out of the 12 mice after the following intervals (counted from the beginning of applications): 10, 17, 18½, 25, 25½, 26, and 40 weeks, respectively. Thus the 50% tumour yield was

reached in 26 weeks, representing a carcinogenic potency (Berenblum, 1945a) of Grade VII. This potency is comparable to that of cholanthrene, and is higher than that of 1,2,5,6-dibenzanthracene.

Of the seven mice with tumours, four subsequently developed malignant growths, which were found histologically to be all squamous carcinomas with atypical growth and local invasion. There were no metastases.

### Benzpyrene Content

Although 3,4-benzpyrene—the potent carcinogen originally isolated from tar (Cook, Hewett, and Hieger, 1933)—is not the only carcinogen present in tar (Berenblum and Schoental, 1947), the fact that it can be identified with ease by fluorescence spectrography (Hieger, 1930) and its concentration in complex mixtures readily estimated (Berenblum and Schoental, 1943) made it desirable to determine the benzpyrene content of liquor picis carbonis.

Using the method of estimation of Berenblum and Schoental (1943), the preparation was found to contain 0.02% of benzpyrene, thus representing a 0.1% concentration in the tar itself (since the pharmaceutical preparation in question is a 20% solution of tar in ethanol). This value of 0.1% is much lower than that found in many of the carcinogenic tars previously tested (Berenblum, 1945b). It would seem, therefore, that benzpyrene accounts for only a small part of the high carcinogenic potency of the preparation observed in the biological tests.

### Discussion

The observation that liquor picis carbonis (B.P.) possesses a pronounced carcinogenic action on mouse's skin accords well with the earlier tests on tar-containing pharmaceutical preparations in use in dermatological practice on the Continent (Sternberg, 1923, etc.). This raises the important question whether its clinical use is not without danger to the patient.

The crux of the problem is no doubt the length of time the patient is exposed to such potentially carcinogenic action. It may well be that no significant danger is associated with its use in short-term treatments. On the other hand, in the case of chronic skin diseases of various types, for which applications of liquor picis carbonis are often continued for many years, the possibility of a late carcinogenic effect may be a real one. Probably the most serious hazard may arise from its continued use by the patient without medical supervision, to alleviate, for instance, some of the recurrent symptoms of occupational dermatitis in industry.

The true hazard, however, can be assessed only by a clinical follow-up of all patients submitted to this form of treatment. In the meantime, avoidance of long-continued application of liquor picis carbonis would be a wise precaution.

### Summary

Liquor picis carbonis (B.P.) as used in dermatological practice, has been found to possess carcinogenic activity when painted on mouse's skin.

The clinical implications of this finding are discussed.

## Medical Memoranda

### A Case of Bilateral Stress Fracture of First Rib

Mass radiography of the chest has called attention to various abnormalities which formerly were found only rarely. Among these is stress fracture of the first rib, usually attributed to the muscular pull of the scalenus anticus during strenuous and often unaccustomed physical exertion.

Roxby Alderson (1944) in 55,451 routine fluorographic examinations found 35 examples among naval personnel, the majority of whom had recently undergone energetic physical training. All but five were seen in males below the age of 25. The fractures were situated just proximal to the scalene tubercle. A notable feature was that only five of the 35 presented any significant history and symptoms—two had "sudden pain" in the shoulder shortly after strenuous physical training, two admitted direct trauma to the affected side of the chest some years previously, and the fifth had complained of a 'sore shoulder' after carrying sacks of coal.

Among 3,000 routine chest radiographs Cohen (1943) found three isolated fractures of the first rib, all without referable symptoms. In one case there was a history of a blow on the chest three months before; in another no cause could be found, and in the third the lesion was attributed to the patient's occupation of carrying heavy boxes on the affected shoulder. Garber (1944) described a man of 54 who had sudden pain in the region of the right shoulder while lifting a heavy milk-container. Subsequent radiographs showed an isolated fracture of the first rib. In his search of the literature Garber found about 64 reported cases of isolated fracture of the first rib due to various causes of which four were due to the muscular pull of the scalenus anticus.

The following case is of interest because of its presenting features and because the stress fracture was bilateral.

#### CASE HISTORY

A Palestine policeman, an Irishman aged 19, was admitted to a military hospital with a story of malaise for three days, with cough and sharp pain in the right upper chest. He had produced a small amount of greyish green sputum. The pain was worse on taking a deep breath and on coughing. There had been no haemoptysis and no night sweats; his weight was steady at 140 lb (63.5 kg) and his appetite good.

Examination showed him to be well developed. The temperature was 101.5° F (38.6° C), pulse 84 and respirations 22. There was no finger clubbing. Movements were slightly reduced in the right upper chest. The percussion note was normal. Scattered moist rales and rhonchi were heard in both sides of the chest.

No pleural friction sound was heard. The other systems of the body were normal to routine examination.

His condition was diagnosed as acute bronchitis and treated as such. After three days his temperature had fallen to normal and auscultation revealed only a few rales in the right chest. But he complained persistently of the sharp pain in the right upper chest and shoulder, worse on breathing and coughing. A radiograph of the chest revealed fractures of both first ribs, symmetrically situated on the two sides and passing through the scalene tubercles (see illustration). On the right the fracture ran transversely across the whole width of the first rib, with a rather jagged line that isolated a tiny island of bone in its middle portion. On the left the fracture extended from the scalene tubercle across about half the width of the rib and the line was smoother. There was no callus formation. It was found that the fractures were better demonstrated if a film was taken while the patient stretched his neck upwards, at the same time drawing the shoulders downwards by pulling on a fixed object.

Further direct questioning revealed that as a commercial traveller in civilian life he had indulged in very little physical

exercise. He had joined the Palestine Police four weeks before admission and had undergone a course of physical training which included an hour of P.T. and a three mile run every morning. Furthermore, he admitted noting pain and discomfort in the right upper chest three days before the onset of the cough. With the coughing the pain had become more severe and stabbing in nature. Pressure over both first ribs, especially the right, produced acute pain. No lesion of the brachial plexus was demonstrable.

Acknowledgments are due to the Director of Medical Services, M.E.L.F., for permission to publish this paper.

### Ruptured Uterus

It is well known that spontaneous rupture of the uterus in labour occurs after previous caesarean section, and that the results to both mother and baby are serious—so serious that some say, "Once a caesarean always a caesarean." If it were usual for rupture to occur this would be the rule everywhere. Fortunately it does not always occur, and there is justification for some modification. If the operation has been for some permanent indication or if the puerperium has been pyrexial, then a subsequent operation is advisable; if not, then admission to hospital is obligatory, but the case may be treated as a trial labour. Such a case is reported—for they are rare enough—to show how rupture can still occur and how insidious it can be.

#### CASE REPORT

The patient, a gravida-2 aged 27, was admitted to the Memorial Hospital, Woolwich, for her second confinement on Dec. 4, 1947. Thirteen months previously she had had a classical caesarean section on account of the extended breech presentation. The puerperium was reasonably satisfactory—a rise of temperature on the 8th, 9th, and 10th days could have been caused by mammary engorgement, and indeed, probably was. The present pregnancy was quite uneventful. The presentation at her last visit was vertex, position R.O.P., and the head was not engaged.

She was admitted at 6.55 a.m. (9 days "late").

Uterine contractions were fair. At 4.30 p.m. contractions were occurring every five minutes. Foetal heart rate was 140. At 5 p.m. she complained of constant pain; the foetal heart was not heard, and the house surgeon was notified. During the next two hours the pain persisted; the pulse remained stationary at 100 but became weaker.

When I saw the patient for the first time at 7.15 p.m. the condition was so striking as to make any other diagnosis impossible. She was white, the pulse was feeble and rapid, the abdomen was distended and tender, and the foetal heart was inaudible. Transfusion and immediate laparotomy were carried out. The abdomen was full of fluid blood, the child and most of the placenta were free and the uterus was gaping from fundus to cervix.

When the child and placenta were removed the uterus contracted. The abdomen was baled out, and the uterus was removed by subtotal hysterectomy, from which operation the patient recovered quite satisfactorily. The baby's heart was beating at birth but it ceased shortly afterwards.

#### COMMENT

There is little doubt that the rupture occurred two and half hours before the laparotomy. The bulk of the bleeding must have occurred then for the abdomen was generally tender from the start and the pulse rate remained constant. The diagnosis of internal haemorrhage was there all the time (probable cause ruptured uterus). KEITH VARTAN F.R.C.S.

## Reviews

### MODERN DERMATOLOGY

*Modern Trends in Dermatology* Edited by R M B MacKenna, M A, M D, F R C P (Pp 432, illustrated £2 2s) London Butterworth and Co 1948

The importance of dermatology as a branch of medicine has been increasingly recognized in recent years. Above all, the authorities responsible for public health have become aware of the large amount of sickness and disability and the tremendous waste of man power caused both in peace and war by skin trouble, and perhaps for the first time in the history of the world corresponding efforts are being made to lessen its effects. These efforts are encouraged by the great advances in treatment provided by the modern chemists and physicists. At the same time those whose mission it is to work in experimental pharmacology and therapeutics appear to be grateful for the opportunities afforded by the easily accessible testing ground offered by the skin for proving, or perhaps disproving, their theories. Again, the vast complexity of the physiology of the skin has of late been increasingly understood. Besides mechanically protecting the underlying structures, it seems also to have the equally important function of providing humoral and chemical antibodies to the countless infections of all kinds. It does much in regulating salt metabolism and in regulating the body temperature, a subject still much more shrouded in mystery than it should be. Another facet of modern dermatology is the recognition of the intimate interdependence of the skin with the rest of the organism. Not only do changes in the skin reflect many general diseases, but severe skin affections also cause disturbances in metabolism. We must, however, make the reservation that the skin is so large an organ that much of it may be put out of action and yet enough remain to carry out its duties fairly efficiently. Of late years too, much has been made of the relation between morbid changes in the skin and the central nervous system, and a causal connexion between them has been eagerly sought. All these aspects of dermatology are considered in the volume before us.

Dr MacKenna has brought together an excellent team of contributors, and the mere recital of their qualifications and the posts they hold demonstrates the interdependence of dermatology and every other department of clinical science. Plenty of problems about the skin remain for everyone to work at. The editor remarks that it is difficult to get young men to study problems of the commoner diseases such as psoriasis and seborrhoeic dermatitis but when we read the work of Professor Stuart Harris on the bacteriology of the skin and that of Stokes and Beerman on the dermatology of to day and tomorrow we begin to see why they prefer contemplating the rarer dermatoses to studying the commoner but less exciting conditions which fill the out-patient departments. The complexities of the subjects which require investigation there are infinite, and it needs the highest scientific acumen to define the right question to ask even before one begins to devise the experiment to answer it. But already much is being done, and those who are interested in all aspects of dermatology will peruse this volume and be in all probability, fascinated by it. For dermatologists it is nearly indispensable, but it is also to be recommended to other physicians who may not be always particularly sympathetic towards this specialty.

To some extent the relative importance attributed to a branch of medicine may be measured by the number of beds allotted to it, and judged by this criterion dermatology in the voluntary hospitals is indeed small beer. Its real claim to consideration in national hygiene may be better calculated by the provision made for treating skin diseases in the fighting Services. It is to be hoped that in the national hospital scheme now slowly coming into operation more justice will be done to it.

To review a book like this in the ordinary way is impossible, but there is one chapter the subject of which has a universal appeal and must be mentioned, and that is the psychological aspects of dermatology. Like other writers Dr Wittkower has been unable to find any principle governing the relation

between neuroses and dermatoses. To the reviewer it seems probable that in many cases skin disease, which always causes great distress of mind to the sufferer, may be the cause and not the consequence of neurosis.

H HALDIN-DAVIS

### A DISTINGUISHED LIFE

*My Life in General Practice* By H W Pooler (Pp 194, illustrated 15s) London Christopher Johnson Publishers Ltd

As the author of this book is an old friend of mine I should have declined to review it if I had not liked it so much, but my critical conscience gives me no qualms when I say that, after reading many books purporting to depict life in medical practice, I put it among the best. It presents the life story of a veteran general practitioner told with art and with gusto. The overriding impression left is that of a modest and happy man successful in his chosen sphere. His interests are wide—for example, he played a distinguished part on the Birmingham City Council, where he was prominent in the building up of its scheme of child welfare in which the city was a pioneer. His work in this sphere led to his being sent on several deputations to the Continent to see and report on what was being done there. His chapters on these visits reveal the author as an acute observer and a ready and interesting letter writer. Like many pioneers he suffered a rebuff at the hands of his constituents, who declined to re-elect him to the council. When he left Birmingham for general practice in Derbyshire, partly country, partly mining, he was a disappointed man. His incurable optimism (this diagnosis of his character is proved correct not only by his own words but by the whole book) soon made him as happy and as useful in his new career as he had been in the city.

Dr Pooler entered his profession in "the hard way" as an apprentice to his uncle, to whom he pays generous tribute. As a dispenser assistant he earned his way through his college career at Queen's College, Birmingham where he was a successful student as he had been at school. After qualification he served in several house appointments. His reminiscences of his old teachers—Sir Walter Foster, Jordan Lloyd, Lawson Tait, Priestley Smith, and others—will be enjoyed, I hope, by many old Birmingham men. But the book should make a strong appeal to all, whether medical or lay, who like to read of the experiences of a man good at his work and devoted to it and always with an interest in the people around him. To members of the B M A Dr Pooler is well known for his long service to the Association as divisional secretary, representative, member of Council and of many committees. The vice-presidency conferred on him last year evidently gave him great pleasure, as it did his friends all over the country. The book contains many good illustrations, some of the best are contributed by a schoolboy grandson of the author and show great promise.

ALFRED COX

### PULMONARY TUBERCULOSIS

*Die Lungentuberkulose beim Erwachsenen Klinik und Therapie für die Praxis* By Dr Hermann Weber Second edition (Pp 417, illustrated 75 Swiss francs) Vienna Verlag Wilhelm Maudrich 1948

This study of "Pulmonary Tuberculosis in the Adult" was originally conceived by Professor Wilhelm Neumann, but owing to his sudden death the work was undertaken by his pupil, Dr Weber. It is intended primarily for those interested in diseases of the lungs, but the author rightly insists throughout on the necessity of co-ordinating this subject with general medicine. The book is divided into two sections, one on diagnosis, the other on treatment. In the former the author surveys the whole field of pulmonary tuberculosis, primary and post-primary. His views are orthodox, up to date, and by and large acceptable to British workers. He emphasizes the importance of a detailed clinical history and a complete systemic examination in diagnosis, but somewhat exaggerates the significance of physical signs and forces it to tally with the radiological picture. While he acknowledges the use of mass radiography, he pays scant attention to the clinically

silent asymptomatic lesion. He discusses pathological investigations in the greatest detail and the lack of space devoted to chest radiology is therefore the more surprising. However, the book is copiously illustrated by radiographs of the chest. Something might have been said of the anatomy of the bronchial tree and the segmental distribution of the bronchi, which workers in this country have shown to be important in thoracic surgery.

The chapter on differential diagnosis is excellent. The author discusses non-tuberculous lung infiltrations and cavitating lesions such as the pneumonias, lung abscess, bronchiectasis, cystic lung, the pneumomycoses, benign and malignant lung tumours, Hodgkin's disease, the leukaemias, Boeck's sarcoidosis, etc. The section on treatment covers present trends in relation to general management, sanatorium regime and collapse therapy in all its forms in a balanced, orderly manner. The section on drug therapy is below standard and there is no mention of streptomycin for example. The space given to tuberculin therapy may be considered by many in this country to be out of proportion to its merits. On the other hand, the author gives a balanced appraisal of prophylactic immunization against tuberculosis.

The book is of unusual interest because it probably represents the views of the post-war Viennese medical school on pulmonary tuberculosis. Its references are fairly complete, but curiously enough there is only one to British literature. One cannot help thinking that some of the chapters might have been better compressed, but the book is a careful study of a vast and significant subject.

PHILIP ELLMAN

### TRICHOMONIASIS

*Trichomonas Vaginalis and Trichomoniasis*. By R. E. Trussell, M.D. With an introduction by E. D. Plass, M.D. (Pp. 277, illustrated 30s.) Oxford: Blackwell Scientific Publications, 1947.

This account of trichomoniasis by R. E. Trussell is essentially a critical review of the literature together with an account of the author's observations. The book contains 277 pages but some idea of the magnitude of the work involved in its compilation can be realized by the fact that there are no fewer than 1,586 references. In spite of this many of the main problems remain unsolved: how does *Trichomonas vaginalis* gain entry to the human body? Does it constitute a venereal infection? Why are females apparently infected so much more frequently than males? Is the organism a true pathogen? These and other questions are not yet answered, but a study of this work will be found most interesting, especially by all those who have to deal with women's diseases.

The organism is difficult to grow in pure culture and there is some evidence that its existence, or at any rate its power to flourish in the tissues, depends on the presence or absence of certain other organisms. There is a good deal of doubt about whether it forms cysts, and it appears to reproduce itself by division into two. It is difficult to inoculate human beings artificially and no doubt the organism is often present in women in a 'carrier' state. Diagnosis is best carried out with a wet specimen, which must be fresh and preferably kept warm; the author recommends various diluents, of which the best seems to be Ringer's solution.

The number of methods used in treatment by various workers is evidence that none is outstandingly effective. The subject occupies as many as 70 pages and the author lists and discusses nearly 200 methods in alphabetical order from rectanilide to zinc sulphate. In general it is necessary first to cleanse the vagina, dry it as far as possible and then apply the chosen remedy: jellies or creams are favoured as the best media. The object should be to restore the normal flora, and there is little doubt that the disease would be easy to cure if it were possible to adjust the pH of the vagina to the optimum. Insufflation is an effective method of applying a drug, but may be dangerous if force is used. Lactobacilli are well reported on by a number of observers. Many of these and other problems still remain unsolved, but the author is convinced that neither oral nor intestinal *Trichomonas* ever infects the vagina. A study of this volume will convey a large amount of information and provide much food for thought.

T. E. OSMOND

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Mesmerism*. By Dr Mesmer. (Pp. 63, 6s.) London: MacDonald, 1948.

The first English translation of Mesmer's *Memoire sur la Decouverte du Magnetisme Animal*.

*Vascular Diseases in Clinical Practice*. By I. S. Wright, M.D. (Pp. 514, 4ts.) Chicago: The Year Book Publishers, 1948.

A manual for general practitioners and senior students.

*The Science of Athletics*. By F. A. M. Webster. (Pp. 333, 15s.) London: Nicholas Kaye, 1948.

A scientific study of many branches of athletics.

*The Principles of Physical Education*. By J. F. Williams, M.D. Sc.D. 5th ed. (Pp. 377, 17s. 6d.) London: W. B. Saunders, 1948.

An account of the aims and methods of physical education.

*Treatment of Heart Disease*. By W. A. Brams, M.S., M.D. Ph.D. (Pp. 195, 17s. 6d.) London: W. B. Saunders, 1948.

A systematic guide for the general practitioner and medical student.

*The "Peleus" Trial War Crimes Series*. Edited by J. Camelson, D.S.C., K.C. Vol. 1. (Pp. 247, 18s.) London: William Hodge, 1948.

An account of the trial of members of a U-boat crew.

*Practice of Allergy*. By W. T. Vaughan, M.D., and J. H. Bluel, M.D. 2nd ed. (Pp. 1,132, \$15.00.) St. Louis: C. V. Mosby, 1948.

The manifestations of allergy discussed from the clinical standpoint.

*Troubles of Children and Parents*. By S. Isaacs, C.B.E., D.Sc., M.A. (Pp. 238, 8s. 6d.) London: Methuen, 1948.

Answers to the questions parents ask about young children.

*Archives of Neurology and Psychiatry*. Edited by A. J. Lewis and S. Nevin. Vol. 15, 1946. (30s.) London: Staples Press (for L.C.C.), 1947.

Articles reprinted from the journals of 1938-40.

*Retinosis and Retinoblastoma*. By P. van der Meer and J. Zeldenrust. (Pp. 83, 40 francs.) Leyden: Universitaire Pers Leiden, 1948.

An account of disorders of the reticulo-endothelial system characterized by cellular proliferation.

*Aids to Embryology*. By J. S. Baxter, M.A., M.Sc., M.D., F.R.C.S. 4th ed. (Pp. 181, 5s.) London: Baillière Tindall and Cox, 1948.

The book has been largely rewritten to incorporate recent knowledge.

*Fortschritte der Biochemie*. By F. Haurowitz, M.D. (Pp. 364, 40 Swiss francs.) Basle: Karger, 1948.

An account of recent advances in biochemistry.

*Lehrbuch der Augenheilkunde*. By J. Babel et al. (Pp. 858, 85 Swiss francs.) Basle: Karger, 1948.

Textbook of ophthalmology, with many illustrations.

*The Clinical Apprentice*. By J. M. Naish, M.D., M.R.C.P., and J. Apley, M.D., M.R.C.P. (Pp. 200, 15s.) London: Simpkin, Marshall, 1948.

A guide to the student starting clinical training.

*The Royal Society Empire Scientific Conference Report*. June/July, 1946. (Vol. 1, pp. 828; Vol. 2, pp. 707, 42s. for both vols.) London: Morrison and Gibb, 1948.

A report of the conference with the papers read.

*Psychology of Personality*. By R. Stagner. 2nd ed. (Pp. 485, 30s.) London: McGraw-Hill, 1948.

The author discusses chiefly the normal personality and its development.

*Aids to Ophthalmology*. By P. McG. Moffatt, M.D., M.R.C.P., F.R.C.S., D.O.M.S. 10th ed. (Pp. 266, 6s. 6d.) London: Baillière Tindall and Cox, 1948.

Includes new material on chemotherapy, and on the treatment of war injuries.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 25 1948

## WORLD MEDICAL ASSOCIATION

The second meeting of the General Assembly of the World Medical Association was held at Geneva from Sept 5-7 under the presidency of Professor E Marquis. The first meeting, held in Paris last year, of which an account was given in this *Journal*,<sup>1</sup> was enlivened by incidents that made some observers doubt whether this new international organization would reach maturity. All such doubts were removed by the conduct of the business of the second General Assembly. The World Medical Association during the past year has through its Council put its hand energetically to the tasks it has set itself. These were stated in the Articles of Association adopted at the meeting in Paris and now printed in a booklet entitled *The Constitution of the World Medical Association*. The first object of WMA is "to promote closer ties among the national medical organizations and among the doctors of the world by personal contact and all other means available. Another of the stated objects of WMA is the establishment of relations with the World Health Organization, Unesco, and other appropriate bodies." WHO, which now has its permanent headquarters in Geneva, has been quick to respond, and the General Assembly listened with close interest to an address read to them by Dr Calderone, who is in charge of the New York office of WHO. In his address, which appears elsewhere in this issue, Dr Calderone said that "by the act of affiliating with the World Medical Association, WHO acknowledges the debt it owes to the medical practitioner." He stressed the identity at certain points of the aims of these two international organizations. The aim of both is, in the words of Object No. 5 of WMA, "to assist all peoples of the world to attain the highest possible level of health," and both organizations recognize that the achievement of this is a step towards the promotion of peace in the world. This again is a further example of the growing belief that contact between similar professional groups of different countries may do much to counteract the aggressive designs of politicians.

While medical men may hope that the millennium will be reached with the conquest of disease and the achievement of maximum health, they may temper their optimism by noting that wars have often been started by nations at the peak of their prosperity. As Dr Calderone observes, Medicine has forgotten to measure the effects upon the social structure of the peoples of the world of the great achievements of medical science and public health during the past fifty years. He points out that if the world population continues to increase at its present rate there will in forty years' time be "another billion hungry bodies and souls over and above those it has to-day." If Medicine has forgotten to measure the effect of its achievements the

creation of WHO and WMA does at least show its awareness of the problem. In the work of these two bodies, and of FAO, medical men have been foremost among professional groups in stepping across national frontiers. At Geneva this month doctors from India, Pakistan, China, Europe, South America, and, last but not least, from the USA overcame the limitations of space and language because they had at heart a common aim.

The President of this year's Assembly was to have been Dr Stuchlik, of Czechoslovakia, and the meeting of the Assembly was to have been held in Prague. After the Communists seized power in Czechoslovakia the Council of WMA decided for obvious reasons that the meeting would have to be held elsewhere, but hoped that it would still be possible for Dr Stuchlik to be President. But another effect of Communism in Czechoslovakia was the abolition of the Czechoslovak Medical Association. This arbitrary act of elimination made it impossible for Dr Stuchlik to be President, although fortunately he was able to be present at the meeting. It is perhaps unnecessary to state that the USSR has not joined the WMA, although it is a member State of WHO, nor has the USSR joined Unesco or FAO.

The General Assembly had before it a document on German medical war crimes, and it was this undoubtedly that prompted it to draft for submission to its member organizations a pledge taking its inspiration from the Hippocratic Oath. This can be ridiculed, and has been by the *Manchester Guardian* as an attempt to subvert this famous medical code. But those who indulge in the tempting and facile game of ridicule might reflect that most national groups would to-day feel disinclined to pay homage to Apollo, and the injunction in the Oath against cutting for the stone would evoke in the mind of the modern doctor merely amused bewilderment. Probably very few medical men know the Hippocratic Oath, and it is rare to find it recorded in histories of medicine, Garrison, for example, refers to it, but does not reproduce it in what is the most authoritative standard work on medical history. We therefore print the pagan version elsewhere in this issue. It is, perhaps, misleading to describe the pledge which has been drafted as a modern version of the ancient Oath. In these days of shifting values a cogent case can be made for drawing up in short and simple terms an ethical code to which medical men and women in any part of the world could respond. If the WMA can succeed in doing this, and if adoption of the pledge could be made part of the ceremony of qualification, it might have the force possessed by the ancient Oath, now merely a curiosity of medical history. The WMA, however, might be well advised to have second and third thoughts on the content of this modern pledge, and if agreement is reached on this by the various member associations great care should be taken in phrasing the different translations. The English translation of the French version that was submitted to the Assembly was not without imperfection.

Another matter that engrossed the attention of the WMA Assembly was social security and its bearing upon medical practice. The Assembly adopted the recommendation of the Council that information on the position

<sup>1</sup> *British Medical Journal* 1947 2 498

of social security in each country should be obtained by means of a questionnaire, that on the basis of this an outline should be made of the "status" of social security in each country, and that the Secretary-General of the WMA should be kept informed of proposed or actual changes in the social security laws of the countries represented in WMA. The Assembly also adopted the recommendation that a permanent committee on social security should be set up. The meeting had before it a number of principles which might be adopted by those countries in which medical care was part of the social security scheme. Of these principles only three were recognized by the USA delegates as generally applicable to the practice of medicine—namely, freedom of choice of physician by the patient and freedom of the patient to change his physician, no intervention of any third party between physician and patient, all medical services to be controlled by physicians. What came out of the discussion on this theme was a general apprehension of State intervention in medicine, opposition to a full salaried service, and doubt whether medical care should be made available free of charge to those who could afford to make a direct payment for it. In addition to setting up a committee on social security it was also decided to set up committees on medical care, ethics, publications, and postgraduate education. These committees will prepare statements to submit to the meeting of the Council of the WMA in Madrid in April next year, which will be followed by the General Assembly in London in the autumn.

It is possible here to make reference to only some of the work of the WMA, but the document presented to the Assembly showed that the Council, through the able guidance of its Chairman, Dr T C Routley, and the hard work of the Secretary-General, Dr Louis H Bauer, had made it possible for the General Assembly to conduct its affairs with efficiency and harmony. It is a commonplace to state that one of the most valuable features of an international gathering lies in the fact that men from different parts of the world can get to know each other. This was indeed true of the meeting at Geneva, and the WMA was much indebted to the abounding hospitality of its Swiss hosts, the Federation des Médecins Suisses and the Medical Association of the Canton of Geneva, and to the indefatigable efforts of WMA's treasurer, Dr Leuch, of Zurich. The WMA is now firmly established on the basis of a sound constitution and efficient administration. It will soon have that necessary outward and visible sign of its existence, a journal, to be edited by Dr Morris Fishbein, the Editor of the *Journal of the American Medical Association*.

## MEDICINE IN THE COMMONWEALTH

A number of medical men from all parts of the British Commonwealth met last week at BMA House at a conference presided over by Sir Lionel Whitby. Most of them had attended the General Assembly of WMA at Geneva during the previous week and were eager to follow the example of the larger organization in fostering personal and professional relationships and in meeting to discuss common problems. The proposed British Commonwealth

Medical Conference is in no sense an offshoot of WMA and certainly does not represent an attempt to form a body within the world organization. The Dominions either have branches of the BMA, or form national medical associations affiliated with it. There is, therefore, this obvious common link between medical men and women in the Commonwealth. Medical men and women in the Dominions have drawn their inspiration from Britain and often return to what they call "home" for postgraduate education and distinctions. They speak a common tongue, and those present at last week's meeting listened with admiration to the fluent and idiomatic use of it made by doctors from India and Pakistan. All these natural bonds hold strongly together those medical men who work in countries belonging as equal partners to the British Commonwealth of Nations. But until now there has been little attempt to foster a spirit that already exists, or to integrate in corporate form the separate units of medical organization in the Dominions. The fact that it is being done now is yet another sign that men and women wish through common association and common aims to stem the forces of disintegration so painfully manifest in a world which modern transport has reduced to the size of a parish.

For two days means of promoting closer contact between doctors of the Commonwealth were discussed by representatives of the national medical associations of Australia, Canada, Ceylon, Eire, Great Britain, India, New Zealand, Pakistan, South Africa, and Southern Rhodesia. To effect this it is proposed to hold an annual conference of representatives of national medical associations or units in conjunction, when possible, with the annual meeting of the association of the host country. The conference, it is suggested, should last three days, and to it each country should send two representatives. The secretary of the host association is to act as the secretary of the conference. If the various Commonwealth medical associations decide to support the project the first meeting will be held in Saskatoon, Canada, in June, 1949, to be presided over by Dr J F C Anderson, the President-Elect of the Canadian Medical Association. In 1950 it is hoped that the conference will be held in Brisbane, Australia, and in 1951 in South Africa.

## RELIEF OF PELVIC PAIN

The object of nerve resection and nerve block for gynaecological disorders is nearly always to relieve pain, and in recent articles in this *Journal* J P Greenhill<sup>1</sup> and Meave Kenny<sup>2</sup> have emphasized the value of these operations in the treatment of inoperable carcinoma. Mr Albert Davis in a paper published elsewhere in this issue now reviews the whole problem, describing the indications, technique, and results of the various operations which have been and still are used to ease the pain of malignant and other conditions. He points out that there have been wide differences of opinion about the value of certain procedures, but that the time is now ripe for an impartial assessment of the results reported both by the enthusiasts for this type of treatment and by those disappointed with the results. Unfortunately the groups of cases treated by sympathectomy, even of common conditions like dysmenorrhoea, are

<sup>1</sup> *British Medical Journal* 1947 2 859

<sup>2</sup> *Ibid* 1947 2 862

<sup>3</sup> *Amer J Obstet Gynec* 1947 53 541

<sup>4</sup> *Ibid* 1948 55 151

small. Moreover, it seems likely that in this as in most things there is a natural tendency to publish good results rather than poor ones, and it is certainly more common to meet verbal than written expressions of disappointment among practising gynaecologists. There seems to be least dispute about the value of intrathecal alcohol injections for hopeless cases of pelvic cancer, though even here the method has the disadvantage that it sometimes leads to urinary and faecal incontinence. Presacral neurectomy is of limited value in this type of case, if only because cancer which is beyond hope of cure is usually causing somatic as well as visceral pain. Moreover, it is open to question whether it is really desirable to carry out an abdominal operation of this kind on a patient who has only a few weeks or months to live. To avoid this difficult decision Greenhill suggested that pelvic sympathectomy should be carried out as a precautionary measure at the initial laparotomy when the findings indicate that the disease is likely to recur and to cause pain at a later date. This can be applied to innocent conditions like endometriosis as well as to cancer.

Perhaps the most difficult problem is to decide the place of presacral neurectomy in spasmodic dysmenorrhoea and of ovarian sympathectomy in painful conditions of the ovary. In the latter connexion Davis mentions that the whole infundibulo-pelvic ligament, including the ovarian vessels, must be cut if all the autonomic nerves are to be divided. This may well affect ovarian function adversely and should not therefore be lightly undertaken in young women. Again, although the ovary is undoubtedly sometimes the site of origin of pain, probably the majority of cases of "ovarian pain" are wrongly labelled. So it is not at all uncommon to see young women who have had not only the ovarian autonomic nerves divided but the whole appendage removed still suffering from the pain which prompted the operation. In his assessment of the value of the presacral neurectomy for dysmenorrhoea Davis reviews the literature and relates his own experience of 86 cases during a period of 16 years, an experience which is probably unrivalled in this country. He claims good results in 54% of his earlier cases, 71% in the later ones, and even better figures for the most recent group. Nervous factors play such a large part in dysmenorrhoea that it is difficult to assess the results of any form of treatment, and it is generally reckoned that all the common procedures—physical exercises, hormones, drugs, dilatation of the cervix, psychotherapy, etc.—give about a 60% cure rate. It would be unfair, however, to compare this with Davis's figures, because his cases were selected and he was dealing only with those in which all other methods of treatment had been tried and failed. The rationale of presacral neurectomy for spasmodic dysmenorrhoea also remains open to question. Is it effective because it severs pain-conducting fibres or because it interrupts motor pathways? Davis takes the view that both mechanisms operate. Nevertheless it is clearly established that the operation does not result in quiescence of uterine muscle, labour following the operation proceeds smoothly and normally as a rule. Nor for that matter is subsequent labour painless, or at any rate not unusually so. Some have suggested that the pain of spasmodic dysmenorrhoea is essentially due to muscle ischaemia (secondary to spasm), so it may be that presacral neurectomy is beneficial in that it improves the blood supply of the uterus. A popular explanation of dysmenorrhoea is to suppose a zone of spasm or increased resistance in the lower segment and cervix, under the influence of adrenergic fibres of the presacral nerve, which is opposed to the detrusor muscle of the upper uterus. This view may not be correct, or at least may require some modification, for Danforth<sup>3</sup> and Schwarz and Woolf<sup>4</sup> have

recently demonstrated that the cervix does not normally contain much muscle tissue, being essentially fibrous in structure. If it is correct, however, then the cases in which presacral neurectomy should give the best results are those which respond well to simple procedures such as dilatation of the cervix and alcohol injection of the pelvic plexus.

The crux of the problem, then, is the selection of cases of dysmenorrhoea suitable for presacral neurectomy. Davis states, and in doing so probably reflects the general opinion among gynaecologists, that the operation should only be considered when the dysmenorrhoea is of the spasmodic type and when all other forms of treatment (including dilatation of the cervix) have failed. This group of course includes those unsatisfactory patients whose symptoms are essentially psychogenic and whose pain threshold is low. Unless these too are excluded the over-all results for any series of cases are likely to be poor. Unfortunately it is these women who are the most persistent in their demand for "something to be done" and who are most ready to agree to an abdominal operation. It is not always easy to exclude these, and a failure to do so may explain why so many gynaecologists are not very impressed with the value of presacral neurectomy. Certainly a rigid selection of this kind followed by a further elimination of those women who refuse the operation means that any one gynaecologist has a comparatively limited experience of the procedure.

## OBSTETRIC ANALGESIA

Pethidine was originally described by German workers as a synthetic substitute for atropine, but in practice it was soon found to possess analgesic in addition to spasmolytic properties. This combination was obviously likely to prove of value for the relief of pain in labour, and it was not long before the drug was being widely used for this purpose. Its safety and ease of administration have been described by many writers, but it has two disadvantages: its action as an analgesic is apt to be uncertain, the relief given by pethidine alone varying considerably from patient to patient, and it has very little effect in inducing amnesia. For these reasons the combination of pethidine with scopolamine has been suggested as a method of improving both the analgesic and amnesic effects. In 1944 Schumann<sup>1</sup> reported favourably on the use of this combination in 1,000 labours, and Dr Hilda Roberts in a paper published elsewhere in this issue (p. 590) records her experience with this method in 500 cases.

The initial dose in her series consisted of 100 mg of pethidine and 1/150 gr (0.44 mg) of scopolamine. This was repeated after one hour, unless the os was more than three-quarters dilated, in which case pethidine alone was repeated. A total of 200 mg of pethidine and 1/150 gr of scopolamine sufficed for the majority of labours, though as much as 500 mg of pethidine and 1/50 gr (1.3 mg) of scopolamine was given to some mothers without apparent ill-effect. Intramuscular administration was preferred, though pethidine was sometimes given intravenously slowly and in dilute solution if labour was well advanced before treatment was begun. The degree of relief obtained was very satisfactory and much better than that given by pethidine alone. Co-operation in labour was on the whole good, though scopolamine caused excitement in a few mothers. For this reason close observation of patients who have received pethidine and scopolamine is obviously essential. The aim was not to produce the full amnesia of twilight sleep but to permit the mother to remember the major part of her labour without any

<sup>1</sup> *Amer J Obstet Gynec* 1944 47 93

<sup>2</sup> *Ibid* 1945 50 542

memory of suffering. No foetal deaths or foetal morbidity could be attributed to the method, though a few of the babies were quiet at birth or slow to breathe, a state sometimes observed when pethidine is used alone. Recovery was always rapid and complete. It was not possible to come to any definite conclusion about the effect of pethidine and scopolamine on the duration of labour, though there is a suggestion that it may actually be shortened. A special study would be necessary to clear up this point. Investigation of uterine contractions by means of an abdominal tocograph showed no changes in their rhythm or amplitude. A slight but transient rise of blood pressure was observed after injection of pethidine and scopolamine, but no depression of maternal respiration could be demonstrated with the dosage used.

The results reported by Dr Roberts are remarkably good, and the method is likely to have a wide appeal, though the need for careful supervision must be stressed in view of the occasional case in which scopolamine leads to excitement. Another possible complication is oedema of the uvula. Steinberg,<sup>2</sup> in a series of 400 labours in which pethidine and scopolamine had been used, observed this condition in three patients, one of them having oedema of the glottis as well. All three showed cutaneous sensitivity to scopolamine, as did a fourth patient in whom oedema of the uvula occurred after the administration of "seconal" and scopolamine. This is probably an uncommon happening and does not appear to have been encountered in the large series of cases receiving pethidine and scopolamine in the obstetric department of the Postgraduate Medical School. Nevertheless it remains a possible complication of the use of scopolamine, and one which should be borne in mind by all who make use of this valuable drug.

### CARCINOGENIC ACTION OF LIQUOR PICIS CARBONIS

The discovery of the carcinogenic action of coal tar on the skin of rabbits and mice was of great consequence in experimental cancer research. Many other carcinogenic agents are now known, but coal tar remains one of the most potent. Twenty to thirty years ago several investigators reported that therapeutic preparations of coal tar in use on the Continent produced cancer of the skin of mice. In a paper published elsewhere in this issue Dr I. Brenblum shows that the same is true of liquor picis carbonis (B.P.). When applied twice weekly it gave rise to papillomata or carcinomata of the skin in half the mice within six months, this represents a moderately high carcinogenic potency.

The presumption that liquor picis carbonis may lead to cancer of the human skin is justified by the observed similarities between occupational skin tumours of man and artificially induced skin tumours of mice. The occupational tumours are attributable to substances which cause cancer when applied to the skin of mice. Following repeated applications of the carcinogenic agent tumours begin to grow after a latent period which depends on the potency of the agent and the frequency of its application. They may first appear long after the applications are stopped, in general the higher the proportion of animals which develop tumours the earlier the onset. Similarly in occupational cancer long exposure to the harmful material precedes recognizable tumour formation, which may be deferred until many years after exposure has ceased. The outstanding difference is in the speed of the carcinogenic process. Carcinogenic agents of high or moderate potency cause skin cancer in laboratory mice, whose life-span is two to three years, within a few weeks

or a few months, in man the same thing happens only after many years. Latent periods of up to 30 years are recorded for occupational tumours of man, and the proportion of exposed individuals developing cancer is usually low.

It is reasonable to conclude that liquor picis carbonis would induce skin cancer in a proportion of human beings provided the exposure was of sufficient intensity and duration. In short courses of treatment the cancer-inducing properties may be ignored. It may be prudent, as Dr Brenblum suggests, to avoid long-continued application for chronic skin diseases pending a more exact appraisal of the risk by observation of patients who have received prolonged treatment. The follow-up of patients should take account of the expectation that cancer will develop only after prolonged applications, possibly many years after the applications have stopped, and in only a small proportion of the patients, and also of a possible difficulty in apportioning blame for a tumour between the therapeutic agent and the lesion to which it was applied.

### STELLATE BLOCK IN PULMONARY EMBOLISM

New indications are still being found for blocking the sympathetic chain with a local analgesic. One of them is the injection of the stellate ganglion in cases of severe pulmonary embolism. Bageant and Rapee<sup>1</sup> describe two cases in which this injection was followed immediately by a profound relief of pain and apprehension and a lessening of cyanosis and shock. The explanation of this favourable result remains obscure, but it can be compared with the relief of pain and improvement in the peripheral circulation which follow sympathetic interruption in cases of blockage of the main arteries in the limbs. Small lesions of the limb vessels, particularly thrombi, frequently cause a widespread increase in local vasomotor tone, the abolition of which may be the reason for the relief given by paravertebral block of the sympathetic chain. It is likely that a similar mechanism operates in the arteries of the lungs, and that occlusion of branches of the main artery is accompanied by a vasoconstriction which increases the burden on the right ventricle and interferes with the flow of blood to the left side of the heart, thus producing a circulatory embarrassment out of proportion to the size of the arterial block. The pain of pulmonary embolism may be due to ischaemia in the affected area or, if the hypothesis recently advanced by Wyburn-Mason<sup>2</sup> is correct, to stimulation of vasodilator nerves. Whatever the mechanism, it would appear from Bageant and Rapee's report that a great improvement in the patient's condition, and probably also in the chances of recovery, can be obtained by infiltration of the region of the stellate ganglion with a local analgesic. The authors recommend that the procedure should be carried out at the earliest possible moment in cases which do not prove immediately fatal, the injections being repeated if the symptoms return or if further emboli develop.

### DISTRIBUTION OF CIRCULATING BLOOD

Accurate knowledge of the minute volume of circulation has been acquired by different methods during the last decade. It is now known that the cardiac output in recumbent man averages between 5 and 6 litres per minute at rest. Several experimental methods have been used to show that about 12 litres of blood flows through the

<sup>1</sup> *Anesthesiology* 1947 8 500

<sup>2</sup> *British Medical Journal* 1948 1 972

kidneys every minute, and 1.5 litres through the hepatic veins.<sup>1</sup> According to Barcroft and Edholm<sup>2</sup> about 900 ml per minute flows through the skeletal muscles, and the recent ingenious studies of Kety and Schmidt<sup>3</sup> show that the blood flow through the brain is also just under 1 litre per minute. The blood flow through the bones is probably very small, Edholm, Howarth, and McMichael<sup>4</sup> suggest an approximate figure of 100 ml per minute. This adds up to 4.6 litres per minute, leaving the very variable skin blood flow to be accounted for, together with the flow through the endocrine glands.

A closely allied problem is the determination of the volume of blood present at any one moment in the various organs of the body. Weiss and Blumgart<sup>5</sup> calculated that the volume of blood in the lung vessels in man was about three quarters of a litre. This calculation was based on the finding that the mean circulation time through the lungs from the right heart to the left was about 10 seconds. If the volume of blood flowing through the lungs in a minute—i.e., the cardiac output—was 5 litres, then the volume of blood in the lungs at any one moment was clearly 10/60 of 5 litres, or 833 ml. A considerably lower figure of 60 ml of blood exposed to air in the alveoli has more recently been calculated by Roughton,<sup>6</sup> using an entirely different method.

Nylin<sup>7</sup> has recently used red blood corpuscles labelled with radioactive phosphorus to estimate the total circulating blood volume. He took the opportunity during removal of the lung for cancer to estimate the blood volume while the lung vessels were clamped at the root. After allowing several minutes for mixing and sampling he released the clamps and new blood samples were again taken. From the resulting dilution of the circulating blood an estimate of the volume of blood in the occluded lung could be made. In three cases the volume of blood in one lung was estimated to be 14–20% of the total circulating blood volume. In a similar manner the volume of blood in the legs was calculated after the release of occluding cuffs round the thighs and found to be 13.6% of the total circulating blood volume. If Nylin's figures are correct, one third of the circulating blood volume (1½–2 litres) would be present in the two lungs—which would appear to be an excessive quantity. It seems doubtful whether the ingenious method contrived by Nylin was really capable of giving a completely accurate answer.

The circulation during pregnancy and in the puerperium is a special problem. It has often been suggested that the placenta acts like a large arteriovenous fistula. The early part of the puerperium is a particularly dangerous period for the mother with heart disease. Brown and her colleagues<sup>8</sup> have attempted to estimate the load imposed on the heart by labour and to study the changes in the circulation following birth. Deductions were by no means easy to make, owing to the variable strains during labour and to the use of pituitrin and ergot afterwards. Blood-volume estimations by the dye method proved to be difficult, and unsatisfactory samples were frequent. It was found that the venous pressure rose significantly during the first 24 hours after delivery, and this was observed particularly in patients who had received ergot. After the initial blood loss during labour the blood volume appeared to increase again on the second day of the

puerperium, and only returned to normal following a post-partum diuresis. The authors think that their observations support the idea that the placenta acts like a large arteriovenous shunt. In a recent study of arteriovenous aneurysms Cohen and his colleagues<sup>9</sup> have shown that the sudden closure of an arteriovenous fistula does not lead to any great immediate relief of strain on the circulation, and its restoration to normal may take many weeks.

## LEAD POISONING IN CHILDREN

Epidemics of lead poisoning among children have been reported from time to time. Such an epidemic in Australia was traced to the ingestion and inhalation of lead dust from painted verandas, and in Japan to the absorption by infants of toxic amounts of lead from the cosmetics and face powder used by their mothers. More recently the use of disused storage battery casings as fuel in poor homes in the USA has caused lead poisoning, and a number of cases in children have been reported from Baltimore<sup>1</sup> and New Orleans.<sup>2</sup>

Children are more susceptible and react more quickly and to smaller doses of lead than adults. The symptoms and signs may also differ in that the most dangerous manifestation of plumbism, meningo-encephalitis, is more frequent than the peripheral neuritis and lead palsy of adults. Children tend to develop a black deposit of lead sulphide on the teeth, this is not identical with the "blue line" seen on the gums in adult lead poisoning. Furthermore, the most rapid and reliable method of diagnosis in children—radiographic examination of the bones—is not applicable to adults, because lead is deposited in radiographically demonstrable amounts only in actively calcifying bone. The characteristic abnormality seen in the bones of children suffering from lead poisoning consists of zones of increased density where growth is most active—the ends of the long bones, the anterior ends of the ribs, and the iliac crests. The dense areas vary in width up to about 0.5 cm, and the width and density are in proportion to the duration and degree of exposure to lead. With increasing growth of the bones the areas become broader and less dense, and the rapid release of lead into the blood stream following cessation of exposure or acidosis resulting from an infection may be followed by renewed lead absorption, producing double zones of density. Zones of metaphyseal density may be produced by other conditions such as vitamin deficiency, congenital syphilis, treatment of the mother during pregnancy with bismuth, and administration of phosphorus for rickets, but none of these is likely to be confused with lead poisoning.

The epidemic in Baltimore was caused by inhalation of volatilized lead. Nineteen children were examined, their ages ranging from 3 months to 20 years, and in fifteen there were abnormal metaphyseal densities on radiographic examination. In general, the younger the child the more obvious were the skeletal deposits, but strangely enough the density of the shadows was not closely related to the appearance of toxic symptoms, especially gastro-intestinal disturbances. The children with the most marked radiographic abnormalities had no history of toxic illness, while those with slighter bone changes had definite symptoms. There was, however, a close correlation between the intensity of the black deposit on the teeth and the radiographic findings. These deposits appear to be almost as good a diagnostic sign as the areas of density in the metaphyses.

## WHO AND WMA SOME POINTS IN COMMON

BY

FRANK A CALDERONE, MD

Director of the New York Office WHO

*We print below a slightly shortened version of an address given by Dr Calderone to the General Assembly of the World Medical Association on Sept 9*

Just a few days ago, on Sept 1, the World Health Organization finally emerged from the embryonic form it has had for two years as an Interim Commission. One of the first acts of this new and potentially important health organization is to welcome the World Medical Association and to establish formal relations with this other potentially important health agency.

Public health stems directly from famous practitioners of medicine not only from this generation but from generations past. There come to mind, for instance, such names as Bernardino Ramazzini, of Italy, who as far back as the seventeenth century wrote a treatise on professional hygiene, Johann Peter Franck, of Austria, who was responsible for the introduction in the eighteenth century of State legislation dealing with hygiene, Edward Jenner, Germany's Max von Pettenkofer and his fight against infectious diseases in the nineteenth century, the Frenchman Hyacinthe Vincent and the prophylaxis of typhoid fever, and, of course, Carlos Chagas, of Brazil, and his work on trypanosomiasis, Simon Flexner, one of the pioneer public health practising physicians of the United States, and the Russian Haffkine, whose work on cholera we all know. These were the actual beginnings of public health. It seems strange that at times medicine has been compelled to remind public health of this very important fact.

By the act of affiliating with the World Medical Association WHO acknowledges the debt it owes to the medical practitioner. The 54 health administrators who attended the Health Assembly here just two months ago were well aware of this debt and directed us specifically to co-operate with the professional medical organizations. It is not surprising that the aims of these two organizations are identical, since it is the nature of the medical man that, given certain data, he will draw certain conclusions. Let us look at both constitutions. Both stress that their aim is to attain the highest possible level of health. The areas of responsibility and action which they delineate comprehend research, problems of standardization, medical education, and the dissemination of health information. In addition, of course, WHO has statutory obligations for international activities such as its epidemiological information and statistical services, and the administration of international quarantine regulations and the like. The two organizations come together again at one important point: they are both aware that the health of all peoples is fundamental to the attainment of peace and security. The similarity of purpose between the two organizations—one intergovernmental, the other purely professional—was emphasized when the Rt Hon Aneurin Bevan stated that "the World Health Organization and the World Medical Association are complementary," and the chairman of your Council, Dr Routley, stated "that without the medical profession the World Health Organization is like an electric grid without current." There can be no question that both organizations must work as a team towards the attainment of the objectives to which they have subscribed.

### A Reversible Equation

What is the main problem we all face together? As you must have recognized, it is the one of peace, and is interwoven with the complete social fabric of man. By this I mean not only man's natural environment but the environment he has created for himself. Thus, the problem includes housing, rural and tropical hygiene, education, freedom from want. One of the most vital of its aspects is proper nutrition and adequate food production for two billions of people who persist in increasing their numbers at a rate of 25 million yearly. We must remember that the total population in the last 300 years has seen a fivefold increase, in the last 100 years alone it has increased twofold.

We take it for granted that the earth can support this increasing population. So far it apparently has. But we must remember that this favourable balance which we have struck momentarily is a reversible equation, that where health is deficient men can produce less food so that the cycle begins to reverse itself. Even in the richest countries of the world we are again approaching equilibrium in the matter of nutrition because of population pressure, perhaps, even, the scale has tipped against us. If that is the case, the trend is toward physical degeneration of the less-favoured population groups, with consequent mental and emotional instability, this in turn expresses itself in the tensions which lead to wars.

Here, then, is one aspect of the general problem I have described to you: the direct relationship between total health and the social mechanism which, in this instance, governs the production and distribution of food. This problem will not be solved by what we do this year or next year, but by the plan of operations which we make in the next five, ten, twenty, forty years, because in forty years, if this present rate of population increase continues, the world will have another billion hungry bodies and souls over and above those it has today. In any long range plan total medicine must begin to play its part. The medical man must extend his already broad horizons, he must work as a member of a team of experts who in unison are pooling all their resources to make man's life possible and good. Such a team must consist of doctors, public health administrators, sanitary engineers, food specialists, agriculturists, forestry experts, economists, bankers. An important place in such a team should be reserved for the leaders of the professional societies, who up to now have tended to isolate themselves in their specialized fields. In the past 50 years medicine has gloried in the accomplishments in the field of science and public health. It has been so proud of these accomplishments that it has forgotten to measure their effects on the social structure of the peoples of the world. It reminds me of the exploitation of forests during the past fifty to a hundred years which has created vast and profitable industries but has led finally to critical erosions of land so that great areas in many parts of the world are now nothing but exposed rock or deserts incapable of feeding people. The very fat of the land has been washed into the sea.

### Interdependence of Medicine

The World Health Organization has recognized the interdependence of medicine with other sciences, social, economic, and political. It has close relations with FAO, with Unesco, ILO, the Economic and Social Council, and the Trusteeship Council of the United Nations. It has formal relationships with non-governmental agencies such as yours, for example, the International Council of Nurses, the International Dental Federation, the League of Red Cross Societies, the Inter-American Association of Sanitary Engineering. It is my belief that the World Medical Association should develop, in addition to its relations with the World Health Organization and Unesco, similar relations with many of the other bodies I have mentioned, especially FAO. Let us examine for the moment the practical applications of this concept of teamwork by experts. Once again I shall take as an example the urgent problem of food. It is quite evident that we can increase production both by developing new lands which are not now being utilized for the production of food and also by releasing for productive use human energy that is now being expended in keeping alive disease-ridden bodies.

The first task is that for the sanitary engineer and the public health man, in conjunction with the agricultural experts, who can open up new areas now infested with malaria, yellow fever, sleeping sickness, kala azar, and schistosomiasis. Let me give you a few figures. There are today 300 million cases of malaria in the world. In Egypt alone, out of a population of 20 million, 13 million are suffering from schistosomiasis. In one belt in China, of an area of 40 miles wide and 200 to 300 miles long, 40 million people are suffering from kala-azar. Whole regions of South Africa are uninhabitable because of trypanosomiasis. It is not too simple to state that in order to open up huge areas for food production we must get rid of these infections. Leaving aside the problems of disease control which such a project would encounter, we must consider the danger to the land itself. These regions which today are unproductive because these

breed disease may be the very areas which protect whole drainage basins against erosion. By stripping these lands of their forests in order to put them into agricultural use we may encourage erosion such as is now washing the friable soils of South America, Africa, and parts of South-East Asia into the sea.

A second task is to take care of people who must now expend perhaps 80 to 85% of their physical energy in combatting the parasites which infest their bodies. They are capable at best of using only some 15% of their strength in working the soil to grow food. This extreme example serves to emphasize the positive function of medicine, which is to ensure that men and women will be born healthy and will remain productive as long as possible.

The whole task, as I see it falls into three natural divisions. In one group of medical problems governmental action has offered the most practical solution. This is true in making use of modern methods which are now available to combat malaria, yellow fever, kala-azar, water-borne diseases, sleeping-sickness, schistosomiasis, brucellosis, industrial hazards and accidents. Here is where the engineer and the public health administrator, following precepts given to them by the medical profession, can get rid of these hazards to life.

A second group requires close co-operation between the medical profession and the Government health agencies. This includes diseases such as tuberculosis, syphilis, gonorrhoea, yaws, smallpox, diphtheria. It is evident here that public health organizations can aid the doctor by educating the public to co-operate in both prevention and active treatment of these diseases.

And finally there is a group in which facilities for diagnosis, hospitalization, and the like are of great importance to the doctor. Where these facilities are supplied by governmental or other sources they enable him better to apply his skills in the fields of paediatrics, obstetrics, internal medicine, surgery, metabolic disorders, developmental disorders, degenerative diseases and psychiatry. Clearly, the co-operation suggested by this broad outline will take time to develop yet we must begin action without delay. Moreover, there are specific points on which we can act immediately. For instance, probably one of the most important objectives for both the World Medical Association and WHO is the proper use of nomenclature in the morbidity and mortality statistics that have been published the world over. It is only with proper nomenclature that it will be possible to arrive at any conclusions about the efficacy of health measures which we are using. By the same token it is important that you help us, as both constitutions foresee, in the standardization of drugs and biologicals, as well as the revision of pharmacopoeias. It is essential that standards of pathological and bacteriological diagnosis be uniform all over the world, that the sedimentation rate mean the same thing in New York, Geneva, Bombay, and Shanghai, that a blood group, as well as the nomenclature that describes it have the same meaning for doctors all over the world. Finally, we must work together in medical education.

In what I say now I am putting forward my personal, not official, views for consideration. Certain favoured areas have enough physicians, but in many parts of the world it is common to find one doctor to 20,000, 40,000, or even 100,000 people. In planning standards of education we must have in mind those areas where there is a dearth of doctors. Let us remember, in making our plans that scarcely forty years ago in New York medical practitioners were being graduated with no more than a high school education and two years of formal medical training. Yet some of these very doctors have made outstanding contributions to medicine. Should the medical profession, then, perhaps begin to think of educating two types of medical practitioner: one for areas which lack medical resources—to be a man or woman with elementary medical and public health training—and the other a fully trained physician who can serve as guide and mentor to the first? To go one step further. It is generally considered wasteful and inappropriate to take health personnel out of their environment in order to train them. To give only one instance: it is said that in the Netherlands East Indies nurses who were trained in the larger cities found when they got back to their village that they were unable to boil water for lack of gas. But Hyndrick's experiences with the same

people forcefully brought home to the doctors the tremendous value of locally trained women picked right out of their native villages, who proved better able to enter the inhabitants' homes and win their confidence than were the doctors themselves. The "diener" has always been famous in laboratories for his all-round usefulness to the researcher. Perhaps we in the medical profession, short-handed as we are in many areas, may need to learn to develop 'dieners' who will serve as medical extensions of ourselves in such fields as health education, hygiene, and nutrition.

The World Health Organization, as it begins its official functional life, needs to be able to count on you in the World Medical Association as the ultimate effectors for any and all projects leading toward total health. In each and every country it is the practising physician who will be making the diagnoses, treating the ills, gearing his efforts into such governmental health projects as are in existence. WHO looks to those physicians to be articulate and forceful figures in their own communities not only as regards good medical practice but also as regards fundamental philosophies of public health, preventive medicine, and the development of sound social thinking. This challenge for all of us, to be in at the beginning of WHO and WMA, opens up such enormous and splendid fields for action that, to me at least, it is exciting and humbling all at once, and I join with you in eager anticipation of what these two organizations, acting in harmony, can achieve.

## LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

It has been pointed out to us that in the postgraduate section of the Educational Number, published on Sept 4, inadequate reference was made to the London School of Tropical Medicine and the facilities which it affords to those seeking the DPH and the DTM & H Eng. This was certainly not due to any lack of appreciation of the work of this great School—the only body which conducts a recognized course for the academic diploma in public health of the University of London. Its work has been described on many occasions in these columns. A long account of its present activities appeared as recently as June 5 (p 1098). As in the case of all the other schools and institutions referred to in the Educational Number, a request was sent for the latest information, and by some mischance no reply was received from the London School, and in the mass of material which was forthcoming from other sources its outstanding position received inadvertently, too scanty notice.

The course of study for the diploma in public health at the School lasts nine months, and the course for the diploma in tropical medicine and hygiene, designed to meet the requirements of the English Conjoint Board, lasts five months. The course in bacteriology lasts one academic year. Special three-monthly courses are given in the principles of medical statistics and statistical methods, and special courses, by arrangement, in physiology as applied to industry. The School's diploma in public health is taken by as many students as those of all the other universities put together. For the DTM & H the School teaches an average of 120 students a year, and for the diploma in industrial health it last year trained 21 students. The prestige of the School with its fourteen full-time professors, was never higher than to-day. In addition to its teaching work, which is continually growing heavier, a great deal of research is carried on under the auspices of the School. A notable instance was the demonstration of an exo-erythrocytic cycle in malaria described in two articles in the *Journal* earlier in the year (March 20, p 547, and June 26, p 1225). A farm at St Albans has been acquired as the field station of the School and here the breeding of laboratory animals on a scale sufficient to supply the wants of the various departments has been undertaken.

Full particulars of the courses at the School and other information are obtainable on application to the Dean, London School of Hygiene and Tropical Medicine, Keppel Street, London, WC 1.

## INDUSTRIAL MEDICINE INTERNATIONAL CONGRESS

The Ninth International Congress on Industrial Medicine, held at Caxton Hall, Westminster, the opening of which was briefly reported in our last issue (p 570), continued its sessions from Sept 13 to 17. The members attending numbered about 750, of whom 270 were from abroad. The presentation of nearly 200 papers was accomplished only by having three or four simultaneous sessions each morning and afternoon. Reception was given by the Government, the Royal Colleges, the British Medical Association, and other bodies, many exhibitions and visits of technical interest were arranged and there were almost continuous film showings—altogether a very full programme.

### Organization of Industrial Medical Services

This subject extended over three sessions, chiefly occupied by descriptions of arrangements obtaining in different countries. Dr P MAZEL spoke of the system in France, where a law was passed in 1946 whereby all establishments employing paid workers whatever their number, are compelled to arrange for medical services. Doctors are chosen by the employers and paid at a rate legally fixed. Dr L GREENBURG related the practice in New York State, with its 52,000 factories, and Dr J G TOWNSEND mentioned the very important part played by the Industrial Health Division of the US Public Health Service in assisting the State departments with detailed studies of working environment. Dr A BRUUS GAARD told the Congress about the Industrial Medical Services Council founded by the Norwegian Federation of Labour, the Norwegian Employees Association and the Norwegian Medical Association. Industrial health services in Finland, where there is free medical treatment not only for the worker but for his family, were the subject of papers by Dr A NYSSONEN and Dr L NORO the latter speaking of the new Institute of Occupational Health at Helsinki, established by the Government in 1946 but not working fully until next year. The function of this Institute will be to protect the physical and mental health of the workers by research, training in hygiene, and attention to environment. A body in Italy, known by the initials ENPI dealing with propaganda against industrial accidents and with the hygiene of labour was described by Professor C PANCHERI and finally Dr N L LLOYD outlined the organization of the medical services of the Ministry of Supply, whose full-time, part-time, and seasonal medical officers numbered nearly 100, with some 140 nurses. The medical needs of small factory units, he said, especially in isolated districts, could be covered satisfactorily only by the part-time services of a general practitioner.

Dr A J ORENSTEIN gave an account of the health services for South African mine workers. A full time medical service has been in operation in South Africa since 1914. The improvement in mortality from certain diseases was illustrated by graphs. The loss of working days in 1947 per person employed was 2.86 as a result of illness and 2.71 as a result of accident. The cost of the service, including hospital costs, is about 52s a year for each African worker employed. Other speakers gave an account of the organization of industrial medicine in the mines of Northern France, in the factories of the Netherlands, and in the leather and rubber industry of Czechoslovakia.

An Australian member Dr J H GOWLAND spoke on the medical officer's contribution to industrial efficiency. What can a medical man supply to industry which is not available from other sources such as the chemist, the engineer, the safety officer? And, again, in what circumstances will the doctor best be able to supply this service? Dr Gowland's suggestion was that while the doctor cannot be expected to know in detail the technique of a particular industry, his clinical knowledge and his professional prestige are of great importance. In Australian industries the medical service is in its infancy, and the speaker asked for criticism and guidance.

### Medical Supervision in Industry

A session devoted to medical supervision in industry was opened by an official of the International Labour Organization, Dr H A DE BOER who said that the greatest service rendered by the international conventions and recommendations enacted during the last thirty years had been the making of medical examinations compulsory for certain groups of workers, both industrial and non industrial. Other directions in which medical science had made its influence felt through legal process had been factory inspection and the establishment of medical services. Dr H P DASTUR reported on medical supervision in Indian industries. The Indian Government had enacted an Employees State Insurance Act, and the medical profession was urging the Government to start institutes of industrial hygiene. Difficulties of an industrial medical department in India arose from illiterate and migratory labour, the poverty of the country, shortage of food, lack of appreciation of the special needs of women workers, and the lack of industrial nurses.

A Belgian organization, the 'Centre de Medecine du Travail et de Psychotechnique' of Couillet, was the subject of a paper by Dr J NOPPIUS. The organization, which covered about 10,000 workmen, undertook clinical radiographic, and laboratory examinations, and there was a department for psycho-

The Right Hon G A Isaacs, MP, Mr T E A Stowell, Professor Pierre Mazel, and Lord Moran, P R C P, at the inaugural session of the Ninth International Congress on Industrial Medicine

logical investigation. It did not undertake treatment but handed over its records to the private practitioner. The majority of abnormalities or diseases which it had discovered related to the pulmonary or cardiovascular systems. Dr Noppius added that the records showed that fairly wide deviations from what was regarded as the normal cardiovascular and respiratory condition were compatible with apparently normal working efficiency, but a thorough knowledge of the individual worker was required to estimate the effect of strains and stresses.

### Student Health Services

From medical supervision in general the discussion passed to the supervision of student health as a somewhat neglected branch of industrial medical care. Dr W G DONALD said that his University of California, which has 24,000 students in its community, had established a health service which diminished the possibility of contagion by compulsory examination on entrance and by vaccination, and controlled epidemics by immediate segregation of the sick in hospital and by putting their quarters in quarantine. It provided facilities for the treatment of the acutely ill and injured. It had a hospital of 180 beds capable of expansion to 430 on emergency, and an adequate medical and surgical staff. An outpatient clinic was open nine hours a day to give care and advice and twenty-four hours a day to deal with emergencies. The cost was borne by the university, and there was no charge to the student.

## Midgley's Medisoaps

*A series of fifteen medicated soaps  
for use in dermatological practice*

*Soap coupons are not required  
for most of the formulae providing  
the patient has a prescription from a  
medical practitioner*

*A new list of Medisoaps is avail-  
able on request*

## An effective and non-irritating DIURETIC

MERSALYL, a highly complex and non-irritating compound of mercury, is one of the most effective and least toxic of the mercurial diuretics for the treatment of ascites and oedema of cardiac origin. In such cases, Mersalyl frequently succeeds when digitalis and other diuretics fail.

Mersalyl-Boots is supplied as a solution containing 10 per cent Mersalyl with 5 per cent Theophylline for injection. As a supplement, Mersalyl Compound Tablets-Boots may be given. The tablets are well tolerated, and

are of value in mild cases and those where injections are undesirable.

AMPOULES 1 cc and 2 cc,  
each available in boxes of 6 and  
100 COMPOUND TABLETS in  
bottles of 25 and 100

## ANAHÆMIN B.D.H.

*in Neurological Complications  
of Pernicious Anæmia*

The hæmopoietic factor as presented in Anahæmin B D H is essential for the prevention of subacute combined degeneration of the cord. Other substances, such as folic acid, will produce an adequate hæmatological response but allow neurological degeneration to appear and to progress unchecked. Potent liver preparations are essential for the satisfactory treatment of pernicious anæmia.

Each batch of Anahæmin B D H is clinically tested before issue.

### SUPPLY AND DEMAND

Today, the demand for London Hospital Catgut is greater than ever before as more and more Hospitals and Surgeons are insisting on sutures made by London Hospital Catgut Supply, in fact, due entirely to circumstances beyond our control, cannot keep pace with demand. Additional skilled labour is difficult to obtain, moreover laboratory equipment, chemicals and packing material are still in short supply. We are, however, doing all

within our power to remedy the position. Labour is being trained, laboratories extended and production increased as rapidly as is humanly possible, and this without the slightest relaxation of our stringent and self imposed standards of quality.

Should you find difficulty in obtaining supplies, please remember that we are doing our best, and requesting our agents to share out all available supplies as fairly as possible.

THE LONDON HOSPITAL LIGATURE DEPARTMENT  
LONDON E.1 ENGLAND

he was in hospital for more than 30 days. The service also controlled the environment, health, and safety of the living and working quarters, and controlled the choice and preparation of food.

In some discussion it was suggested by medical officers in university centres in this country that the student was subjected to a special occupational stress in the shape of recurrent examinations—a stress to which young people in other occupations were not subject—which often brought about a lowering of health standards and sometimes breakdown. Dr W N LEAK said that the effort to improve student health should begin before the student's university career, and some approach should be made to head masters of county or secondary schools who tended to "push" students.

Dr DE VERICOURT spoke of a student health scheme in Paris which is run by the Ministry of Education. It included preventive medical control of all students, who were examined on entry into the university, and subsequently at certain periods. The examination employed laboratory and x-ray methods, and vaccination was required. In cases of tuberculosis the student was sent to a special sanatorium, where he had the opportunity, if he could avail himself of it, of continuing his studies, and from there he was discharged by easy stages to convalescent homes. In reply to a question Dr DONALD said that of the Californian students who came under the health service 60 or 70% in his judgment, were fit for military training.

#### Training of Industrial Medical Officers

Professor J M MACKINTOSH presided over a session for a discussion on the training of the industrial medical officer. Professor R E LANE said that the whole time industrial medical officer should have spent one year in postgraduate study in preparation for his work. Too narrow a specialization should be avoided. The preventive approach must be stressed all the time. Teaching might be by means of lectures and demonstrations, seminars, symposiums, and syndicates—meaning by this last the splitting up of a class into groups under a leader who, after discussion in the group, formulated their conclusions before the whole class. Drs R HUSSEY and S F MEEK put forward the American standpoint. Their view was that a formal educational programme was necessary for the industrial medical officer and that it should include periods of practical experience in the medical departments of commercial and industrial concerns. Professor R C BROWNE described the department of industrial health initiated by the Nuffield Foundation in the University of Durham in 1944. First priority was given to research and second to teaching, and the departmental effort was distributed about equally to the bedside, the laboratory, and the factory. Surveys on miners' myasthenia and the industrial health of workers were in progress. Throughout the whole of the research and clinical practice of the department there was the closest integration of clinical, industrial and social aspects.

Dr R S F SCHILLING put forward the view that what was needed in teaching was fewer general principles and more detail. He also said that the walls between the departments of public health and of occupational health should be thin, and there should be a communicating door. Dr W J LLOYD mentioned the value of getting undergraduate students to spend a morning at a factory. An Indian delegate suggested that the industrial medical officer should be first required to serve for from three to six months as a lay inspector of factories.

A subsidiary discussion dealt with industrial medicine and the law. Mr MOELWYN HUGHES K.C., and Dr P PRINGLE, expounded English law so far as industrial medicine is concerned in particular the major provisions namely, the Factories Acts and the Acts dealing with shops, ships, mines, and a few specific industries. The minimum requirements of occupational health prescribed by these Acts were supplemented in recent legislation by provisions for developing medical services through joint consultations on matters affecting health. Other speakers reported on labour legislation in Italy and in Argentina. Dr CATHERINE SWANSTON reviewed the protective legislation for women and young persons in industry. Even now the law as it stood in relation to women and young persons was in many respects out of date, illogical, and uneven in its application and required examination and revision.

#### Occupational Health and Rehabilitation Services

Dr G E GODBER gave a brief exposition of the British National Health Service. The greatest commendation the new service had received, he said, was that few people had noticed the change. The service had many gaps, but at least it had begun. Asked whether the available doctor-power and the actual cost of the service had been taken into consideration, Dr Godber said that the new service did not suddenly impose an enormous new burden on either financial or medical resources. It made the best use of what was available, and provided for development as resources increased. At least an even distribution was secured.

Dr G DECHARNEUX gave an account of a factory service at Liège of which he is chief medical officer, and which included, in addition to care of accident cases, specialist consultations and a medico social service. He said there was a cordial relationship between the factory doctor and the general practitioner, the former handed the cases over to the general practitioner for treatment.

The placement of disabled persons was discussed by Dr F E POOLE on the basis of the experiment originally developed at Lockheed, which had been used successfully there in placing over 20,000 'limited' employees. He pointed out that the majority of disabled persons had more ability than disability. Pre-placement examination should take cognizance not so much of any specific defect as of deficiency in the applicant's capacity which prevented him from performing certain types of work with safety. The problem was to match the 'limited' worker to the job he could perform without danger to himself or others. A Californian doctor, Dr B HANMAN pointed out that placement required a knowledge of the education, interests, aptitudes, temperament, and personality of the individual. Within each disability there were variations as wide as those in the general population. It was not sufficient to give a one-armed man a one-armed job.

Professor T FERGUSON described the development on the industrial estate at Hillington, near Glasgow, of a sheltered workshop for severely disabled men. The aim throughout had been to keep medical supervision so far as possible in the background and to run the enterprise on ordinary industrial lines. Benches were arranged so as to accommodate the disabled worker, doors were specified of a certain width to admit invalid chairs, and so forth. After two years the success of the venture was apparent. Over-all absence was only 7.5% of the total number of working days. The output had gradually risen and had become stabilized at about the tenth month. The directors considered that the financial result justified reasonable confidence in continued success. The best testimony was the happiness, enthusiasm, and sense of corporate life of the workers themselves. They worked as a team, helped each other, and developed social interests outside the factory.

#### Toxicology

Five sessions were devoted to toxicology. The first paper, by Dr A JORDI, described cases of psychic disorder observed in Switzerland as attributable to industrial poisoning by lead, mercury, and many organic solvents. The symptoms were loss of memory, slackening of mental processes, and nervous irritability. Treatment by vitamins B and C had proved helpful. Two Italian medical men mentioned the occurrence of epileptic fits in persons handling trimethylenetrinitroamine, an explosive obtained by treating urotropine with nitric acid. Of some 20 workmen exposed to the dust, 17 had convulsive fits or attacks with loss of consciousness, isolated or repeated.

The clinical aspects of hydrogen sulphide poisoning as seen in the Swedish shale industry were discussed by Dr G AHLBORG. During the last five years there had been 100 cases of acute and subacute poisoning, 20 of them with sequelae which could be followed clinically. Dr E BERG spoke of the early diagnosis of lead poisoning in Denmark by means of blood analysis. The blood lead, he said, was the most precise indicator of lead absorption and therefore the most important diagnostic criterion in prophylactic control. In Norway, according to Dr E THISEN-EVENSEN hexanitrodiphenylamine was liable to set up eczema in those working with it. Two Swiss physicians brought forward a few cases of bronchial asthma caused by  $\alpha$ - $\beta$ -dichlorodithiol

ether among workers in a chemical plant who had been exposed to high concentrations of this substance. Another Swiss observation was that high altitude was a means of treatment of chronic benzol poisoning. In 15 cases patients suffering from chronic benzol anaemia had been sent to Montana 1,800 m above sea level with good effect in every case.

Professor RENE FABRE discussed the toxicity of trichloroethylene and the symptoms of chronic intoxication caused by it, and emphasized the importance of determining the trichloroethylene content of the urine as a measure of its penetration into the system. Dr K REJSEK described an allergic illness in employees in a Czechoslovakian factory manufacturing castor oil. The illness was characterized by severe conjunctivitis and acute dermatitis.

British anti-lewisite was reviewed by Professor R. A. PETERS. Clinical trials with B. A. L. had proved effective therapeutically in a high proportion of cases in arsenical dermatitis. It had also an important therapeutic action in poisoning by mercury compounds. Professor S. CACCURI said that poisoning from TNT in munitions factories was often seen in Italy. The chief symptoms were blood changes and hepatitis. Experimental research had shown that TNT produced erythropenia, leucocytosis with eosinophilia, diminution of platelets, and prolongation of clotting time. Professor DERVILLE and Dr ROBERT related a few cases found in France of intoxication by TNT fumes or dust. The pathological effects consisted of nervous and digestive disorders and relapsing dermatitis. An unusual outbreak of mercurialism in an Italian felt-hat factory was described by Professor VIGLIANI and Dr BALDI, the principal symptoms being tremor, psychic excitability, gingivitis and rheumatic pains. Thanks to strict medical control and many hundreds of quantitative analyses of the mercury content of the fur, the water in the shrinking-tanks, the urine of the workmen and the air, new cases now hardly ever appeared.

### The Newer Metals

Great interest was shown in a discussion on the new metals especially beryllium. Professor W. MACHLE defined berylliosis as a general disease, characterized chiefly by pulmonary symptoms resulting from inhalation of finely divided beryllium compounds. He gave a clinical study of 60 cases occurring in the United States. Dr J. M. BARNES described an experimental investigation into the toxicity of beryllium. The average lethal dose, injected intravenously, for mice, rats, and rabbits was 0.75 mg per kilo. Death occurred in two to four days with liver necrosis but small quantities had been ingested for a year by rats and mice without producing any evidence of disease or pathological changes in the tissues. Dr C. R. WILLIAMS analysed the occurrence of about 100 chronic cases in the United States and their relation to the industries in which they occurred. He said that correlation of cases with environment still remained the most important evidence against beryllium.

In further discussion Dr J. N. AGATE suggested that berylliosis might become so serious that it would be well to press for it to be made notifiable. It would be a great advantage to get such legislation through before a really big crop of cases occurred. He also said that the liver biopsy procedure should be used wherever possible. Dr PETER NASH said that until the American experience which had just been related to the Congress no one had discovered any correspondence between the intensity of the exposure and the incidence of the disease. Dr H. LISCO said that in Chicago cases of beryllium poisoning were found in people who had been exposed for a very long time before giving evidence of any pathological manifestation. In his view beryllium should be treated as a radioactive substance so far as air contamination was concerned. Dr NIXON urged that individuals who had been exposed should be followed up for a long time after exposure had ceased. Lesions might appear as long as ten years after exposure.

Dr A. J. VORWALD and other American workers urged caution before applying in the clinical field the results of experimental investigations. There was still doubt whether some additional factor other than beryllium itself was not the precipitating agent. After a number of years' experimentation with beryllium it had not been possible to produce the classical unit lesion in animals. Dr C. R. WILLIAMS, an American worker, said that it did not necessarily require more exposure to produce an

acute case than to produce a chronic one. The maximum allowable concentrations had still to be determined and pending such determination it would be most unwise to give the authorities any figure which they could hang their hats on.

### Occupational Carcinoma of Bladder

Diverse views were expressed on the problem of bladder tumours in the dye industry. Dr G. H. GEHRMANN and two American colleagues presented evidence that aniline does not produce bladder tumours. Beta naphthylamine was the only compound with which they had been able to produce tumours experimentally. The term aniline tumour of the bladder was a misnomer. Dr G. DI MAIO, who spoke in Italian, had found on urological examination of 186 workers some 34 tumours and 68 cases of congestion, most numerous among those employed in the benzidine department, and decreasing in the other departments, being lowest among the workers with aniline. Two other Italian contributors also said that benzidine had the highest carcinogenic power, beta-naphthylamine coming next, and aniline and the other amines being much less potent. A worker in Basle, Dr A. MÜLLER, on the basis of 132 cases of industrial disease of the bladder, found benzidine and beta naphthylamine most prominent as causal factors. Preventive measures—combating dust by suitable construction of plant and buildings, replacing dangerous bases by innocuous salts and practising cystoscopy as a routine for all particularly endangered—had brought about the disappearance of several cases; other cases had been discovered in an early stage and timely treatment undertaken. Dr GEORGINA BONSER said that experimental investigation of this industrial disease lagged far behind clinical knowledge, and the reason was the failure to find a suitable experimental animal. Dr C. BELLESINI said that benzidine had been produced in a dye factory in Upper Italy during the last 15 years in such a manner that not a single case of tumour of the bladder had occurred among the workmen. These last two speakers declared that there was no real evidence that benzidine was carcinogenic.

Dr W. M. GOLDBLATT said that this disease was local to an industry. Men died of it and died in considerable numbers. Those who maintained that it had no relation to occupation should undergo a process of corrective education. The time had come when the disease should be compensable. It was most important in defining loss of faculty in relation to this disease not to define it in relation to a particular process. In spite of all the negative experiments the men who died had worked with benzidine or with aniline. To define loss of faculty only in relation to beta naphthylamine would be cruel and unjust. He knew of one factory where from 14 to 16% of the men had had haematuria at one time or another. Many of them were going to die of carcinoma of the bladder, though by medical supervision and treatment their lives might be prolonged. They should be compensated by law, not left to receive an *ex gratia* payment from employers. Many who left the factory with a completely normal bladder so far as the cystoscope could determine, and showing no symptoms developed a tumour years afterwards. Dr Goldblatt analysed a series of 102 cases, and indicated the relatively early ages at which these tumours appeared as compared with the occurrence of bladder tumour in the general population. He concluded by asking:

Why should it only be the bladder? The answer was that it was not sometimes it was the kidney, as proved by pathological specimens.

### Pneumoconiosis and Other Lung Diseases

Many papers on pneumoconiosis were presented. Professor J. GOUGH and Dr J. E. WENTWORTH spoke on the pathology of the condition among coal workers in Wales and demonstrated a technique they had devised for cutting and mounting as permanent preparations thin sections of the entire lung. Dr A. BRUUSGAARD described a condition found in silicon carbide workers in Norway, 10 out of 32 on a plant producing carborundum showed changes in the lungs which could be detected in chest radiographs. Two Czechoslovakian workers described a pneumoconiosis due to exposure to the dust of stannous oxide. Silicosis in Switzerland was the subject of a paper by Drs F. LANG and A. STOKLY. Out of a total of 1,447 persons notified between 1932 and 1946, about 25% had died.

25% were on pension, and the remainder were still at work. About half the sick ended with an added tuberculosis. Workers from Belgium, Sweden, and the United States gave their experiences.

Dr T A LLOYD-DAVIES described a pneumonitis found in men exposed to the dust of manganese oxide. His conclusion was that the inhalation of the manganese-containing dust, without the operation of any additional factor, caused pneumonitis. Dr K M A PERRY mentioned an acute respiratory illness in which radiographs showed miliary shadows throughout the lung fields among workers in a factory using bagasse, which is sugar cane after the sugar has been removed. Finland, apparently, is the country in which mass radiography is most popular. Dr CARL WEGELIUS said that about 70% of the population of Finland over the age of 10 had been examined—the highest known figure in mass radiography to date—and many people had been radiographed five times. The mass radiographs were collected in one central archive, where they were read by competent radiologists.

Metal fever produced by copper dust was described by Dr E H SCHIOTZ. It is a fever resembling "brass-founder's ague." The "copper fever" of Sweden and Norway corresponds to the "zinc fever" of Germany and the United States and the comprehensive designation "metal fever" was suggested. On this point Dr VAN LUIJT instanced five cases seen in Holland in men who, while unloading ships, had inhaled a large quantity of the fine dust of copper sulphate snow used in agriculture and had shown symptoms lasting in an acute form for two months.

### Industrial Hazards

The hazards of specific industries occupied three sessions. Dr GEORGE FLETCHER spoke of byssinosis as found among card-room workers in Lancashire; it was an affection of the lungs which gradually developed over the course of years. Dr G BUCHANAN reported on the occupational hazards of the dock worker, more especially his liability to accident: an average of 8 000 accidents were reported yearly in dock labourers. Professor E A PALUCH set out the haemoglobin levels among certain occupational groups in Poland in the immediate post-war period. Industrial groups showed a mean haemoglobin level from 25 to 30% lower than that in corresponding English groups, whereas the haemoglobin level among agricultural workers in both countries was about the same. The leather trades came in for special mention. An account was given of various complaints found particularly among those engaged in shoe manufacture in Czechoslovakia. Dr ALICE STEWART gave an account of the incidence of pulmonary tuberculosis in the Northamptonshire boot and shoe industry. She had found that in this industry the incidence of active tuberculosis was not uniformly distributed: men and women employed in large crowded workshops contracted the disease more frequently than those who worked in small rooms or less crowded rooms.

The dust problem in mines was the subject of a series of papers, among which should be mentioned Mr H H WATSON's study of the variation in dust conditions at the coal face. Potential hazards in the handling of radiant energy had a session to themselves. Dr G FAIR of the United States, laid down certain permissible limits of exposure to ionizing radiations. With ordinary x rays or gamma rays he suggested a permissible limit for exposure of the whole body of 0.3 roentgens per week, measured in air, for exposure of the hands only, 1.0 r per week, and for a single exposure of the whole body in a lifetime, 25 r for persons from 21 to 45 years of age and 50 r for persons over that age.

### Surgical Conditions Found in Industry

Mr WILLIAM GISSANES outlined the organization of an accident service was followed by a discussion in which Dr R A TREVETHICK and Dr H MOORE gave their experiences. The latter said that he was concerned as he went about the country to find the large number of excellently equipped dressing stations which were being used only for the dressing of simple injuries while all other cases went automatically to the general or accident hospital and often were not seen at the station at all the man coming back certified fit for his job.

He wished to see all cases of incapacity, if they were not of more than moderate degree, treated in industry, and also to see all cases that had been treated as out-patients in hospital coming back to industry for full treatment afterwards, provided the facilities were there. Dr GOEDERTIER said that in Belgium they did not like sending their cases of injury to hospital, preferring to treat them locally if possible.

Dr F FRIEND analysed the radiological appearances in 500 unselected cases of low backache and sciatica seen at Manor House Hospital. He declared that routine examination of the lumbo-sacral region in young people entering industry was as important as x-ray examination of the chest. Professor E D TELFORD discussed the pathology of "dead hand," and illustrated the causes, incidence, and contributory factors by referring to an extensive outbreak in an aero-engine factory. Although there seemed to be at present no means of abolishing the disease, various devices were suggested which might reduce its incidence. Drs S H HARRISON and ELIZABETH TOPLEY reported on an investigation made with a view to defining the value of systemic penicillin in finger-pulp infections. They concluded that there was evidence that local penicillin at operation and systemic penicillin for a complication were both much less effective than systemic penicillin started before operation. Dr R A TREVETHICK described investigations which had taken place at a branch of United Steel Companies into the incidence of sepsis in heavy industry and discussed prevention and treatment.

Professor W MACHLE and Dr F GREGORIUS reported on the occurrence of cancer of the respiratory system in the chromate-producing industries of America. A high death-rate from cancer was found among exposed workers. 23% of all deaths in the industry during the period of study were reported to be due to cancer of the respiratory system. Dr A THELWALL JONES said that among most surgeons there was no doubt at all of the considerable increase which had taken place in the incidence of bronchial carcinoma in men, and Sir CECIL WAKELEY who presided, said that even labourers in orchards were now liable to get this condition in the course of their employment owing to the universal adoption of the use of arsenic, copper sulphate, nicotine, and tar oil.

A number of papers were read on dermatological conditions met with in industry. Two French investigators described intolerable nocturnal pruritus among carpenters using iroko wood or African oak. Dr W BLOOD spoke of the erysiploid of Rosenbach, an occupational disease of the skin usually affecting the fingers or hands, and occurring among workers in the catering and allied trades. He described seven cases which had been successfully treated with intramuscular penicillin. Three workers described granulomatous skin lesions produced by beryllium compounds and showing a marked resemblance to sarcoidosis.

### The Workers' Environment

Sessions were devoted to various questions affecting environment—lighting, architecture, thermal comfort, and other factors. Discussing thermal acclimatization to hot climates, Dr MACDONALD CRITCHLEY said that the pathology of acclimatization was not well understood, and the psychology of it hardly touched upon at all. Tropical acclimatization was far from being a purely physiological mechanism. The acclimatized person had learned to adopt certain attitudes of mind, and the degree of his hardness, the state of his thyroid, and the number and distribution of his sweat glands might all be highly important in determining acclimatization. As for hardening for cold, he pointed out the curious fact that Arctic explorers were very much worse off in their second year in the Arctic than in their first. Acclimatization to the jungle (moist heat) implied some measure of acclimatization also to the desert (dry heat). It had not infrequently been noted that people home from the Tropics stood the cold rather better than the average person in this country. In Scott's expedition to the Antarctic the man who withstood the cold better than the others was an officer of the Indian Navy who joined the expedition in the Persian Gulf.

Illumination in factories and coal mines was discussed, and there was a symposium on colour vision. One contributor, Dr W D WRIGHT, said that from 4 to 8% of the male population had defective colour vision, and therefore pre-vocational tests were highly desirable, to be undertaken either at school

or in industry. Dr L G NORMAN suggested that the mass testing of groups of school-children for colour vision would present a number of difficulties and advocated the establishment of centres at which full colorimetric tests might be carried out.

Papers were also presented on atmospheric pollution, on the problem of fatigue, on electrical accidents, on job placement and analysis, and indeed on every aspect of industrial health.

### Concluding Session

The concluding session was presided over by LORD WEBB-JOHNSON who congratulated all concerned on a successful Congress and paid a tribute to the pioneers in industrial medicine. Mr G R STRAUSS M.P. Minister of Supply said that, although Great Britain was perhaps not the first country to concern itself nationally with the health of the worker, he believed there were few countries where so much care was taken to secure health and safety in occupation and to look after the worker when sick and nurse him back to health. The National Health Service made no less necessary the Industrial Medical Service and he was sure that medical men in industry would co-operate willingly in the National Health Service. Mr Strauss referring to a series of papers on hazards and prevention in relation to radiant energy which had been presented to the Congress mentioned that his Ministry's Atomic Energy Research Establishment at Harwell would soon be producing enough radioactive isotopes to supply the entire medical demand in Great Britain and leave a surplus for export to meet the world demand.

Sir EWART SMITH a member of the Advisory Council on Scientific Policy, followed with an address on the contribution of engineering to industrial health, and the Congress closed with complimentary addresses by Professor P MAZEL and Professor L CAROZZI vice-president and secretary-general respectively of the Permanent International Commission for Industrial Medicine which was founded at Milan in 1906 and includes representatives of twenty five countries.

## SOCIETY OF MEDICAL OFFICERS OF HEALTH

### MR BEVAN'S ADDRESS

The Society of Medical Officers of Health held its annual dinner—the first since 1938—on Sept 16. The President of the Society, Dr Frederick Hall CBE was in the chair, and the principal guest was the Minister of Health, the Rt Hon Aneurin Bevan, M.P.

In proposing the health of the Society Mr Bevan referred in congratulatory terms to the launching of the National Health Service. The period of controversy, he said, was now behind them, and they were all looking forward to fruitful co-operation. This was a great experiment whereby a State-financed machine was co-operating with voluntary administration for the benefit of the public and the advancement of medical science. He fully expected that as the months went by many defects, some of them never foreseen, would be revealed, but the usual British capacity for improvisation and adaptation would make them good. One section of the community more harassed than any other by the possibility of heavy expenditure in serious illness was the middle and professional classes and Mr Bevan had been afraid that unwholesome propaganda might lead them to stay outside the Act. That danger was past. Already between 92 and 93% of the population had signed up with the doctors; signatures were coming in at the rate of 150 000 a week and it appeared that by the end of the year practically the whole population would be in—This means that the health service will be a classless service, and every section of the community will be in full enjoyment of its benefits.

Mr Bevan went on to pay a tribute to medical officers of health who had done a magnificent piece of work in getting ready for the Service and helping to launch it. The development of the Public Health Service during the last hundred years was one of the great features of British history. The relation of the Ministry with medical officers of health was quite special. The Ministry knew the value of these officers and knew that

they would continue to serve as the unifying principle in the administration of the health service.

Dr Frederick Hall in response spoke of the great importance of preventive medicine, which must be emphasized all the time if the National Health Service was to succeed in full measure. He assured the Minister that medical officers of health would give every support to these new developments. In reply to the toast of 'The Visitors,' proposed by Dr J Greenwood Wilson, Dr H Guy Dain, Chairman of Council of the British Medical Association, spoke of the good relations between the Association and the Society. Working together they would do everything possible to ensure that the remuneration of medical officers of health was in line with that of other sections of the profession. "One thing the Minister has done has been to solidify the profession, and this would enable the best results to be obtained from the Service." Sir Wynne Cemlyn-Jones responded for the guests who represented local authorities and said that local authorities also would do everything possible to assist in bringing the new service into full operation.

## Nova et Vetera

### THE HIPPOCRATIC OATH

The attempt of the World Medical Association to draft a pledge which can be adopted by medical men and women as a short code of ethics has given some publicity to the Hippocratic Oath, and also to the mistaken idea that this Oath is sworn to by the newly qualified doctor. It is reproduced in very few histories of medicine, and so we print below the translation of the Pagan Oath given by Mr W H S Jones in his book *The Doctor's Oath* (Cambridge University Press, 1924). There are other versions of the Oath, one, for example, 'in so far as a Christian may swear it, and also an Arabic version.

#### Pagan Oath

I swear by Apollo Physician, by Asclepius by Health by Heal-all and by all the gods and goddesses, making them witnesses, that I will carry out, according to my ability and judgment, this oath and this indenture.

To regard my teacher in this art as equal to my parents to make him partner in my livelihood, and when he is in need of money to share mine with him, to consider his offspring equal to my brothers, to teach them this art, if they require to learn it, without fee or indenture, and to impart precept, oral instruction, and all the other learning, to my sons to the sons of my teacher, and to the pupils who have signed the indenture and sworn obedience to the physicians' Law, but to none other.

I will use treatment to help the sick according to my ability and judgment, but I will never use it to injure or wrong them.

I will not give poison to anyone though asked to do so nor will I suggest such a plan. Similarly I will not give a pessary to a woman to cause abortion. But in purity and in honesty I will guard my life and my art.

I will not use the knife either on sufferers from stone, but I will give place to such as are craftsmen therein.

'Into whatsoever houses I enter, I will do so to help the sick, keeping myself free from all intentional wrongdoing and harm especially from fornication with woman or man, bond or free.

"Whatsoever in the course of practice I see or hear (or even outside my practice in social intercourse) that ought never to be published abroad, I will not divulge, but consider such things to be holy secrets.

Now if I keep this oath and break it not may I enjoy honour, in my life and art among all men for all time, but if I transgress and forswear myself, may the opposite befall me.

Mr Jones also gives the oaths adopted by the Faculty of Medicine at Montpellier, and that taken by Glasgow medical students on graduation.

### Prevention of Dust Diseases of the Lung

SIR—Professor A. Meiklejohn (Aug 21 p 399) rightly re-emphasizes the urgent need for a definition of the 'dangerous' stage of pneumoconiosis at which a man must be advised to leave a dusty working environment in order to be safe from serious consequences. I do not believe that in defining this stage as 'pin-hole nodulation' Drs A. Harper and J. M. Morgan (Sept 11, p 530) really get us any further for this is another quantitative term like Hart and Aslett's 'reticulation' and leaves unanswered the question: How much pin-hole nodulation? or, How much reticulation?

Drs I. Davies and K. J. Mann have this week presented to the Ninth International Congress on Industrial Medicine a proposed classification of radiographs of coal miners' pneumoconiosis which contains the quantitative element which has hitherto largely been missing from schemes of radiological classification of the pneumoconioses. Instead of giving descriptive terms to the various degrees of simple pneumoconiosis they use four numbered categories of increasing intensity. These categories are not merely defined by verbal definition but by standard radiographs.

In another paper which I and my colleagues contributed to the same Congress we record that out of 103 cases in which we have films showing the earliest stage of progressive massive fibrosis the associated simple pneumoconiosis is of category 3 in all but two cases. In these two cases it is only just below this category. We therefore suggest that men could be almost completely protected against developing massive fibrosis and its attendant disability if they were advised to leave a dusty working environment before they reach category 3 pneumoconiosis. It is because men in this stage are nearly always symptom-free that they can only be detected and given appropriate advice by routine periodical examinations. It should be noted that, with the institution of efficient dust suppression methods leaving a dusty working environment does not necessarily mean leaving underground work.

I still contend that men who have already reached a more advanced stage than category 2 simple pneumoconiosis may be advised to remain at their accustomed work under supervision if they so desire, so long as they have not got open tuberculosis. Some evidence in support of this contention is given in our paper referred to above. Drs Harper and Morgan only confuse the issue by introducing a completely invalid analogy between crush injuries of the hand and pneumoconiosis. If a man will be economically and psychologically better off by staying at work and if there is good evidence that he will not prejudice his health by so doing, then surely he should be reassured and advised to do so—I am, etc.,

### Control of Dental Caries

SIR—Your leading article (Sept 11, p 522) raises several interesting points concerning a subject that is badly neglected in the medical and scientific world. However, the general conclusions are rather negative and may, I think, be a little misleading. For example, you refer to the 40% reduction in caries incidence resulting from local fluoride applications. It is sometimes supposed that this figure refers to the number, or proportion of some population, who suffer from caries. It really refers to the number of new carious lesions detected in the teeth of American children in a certain time interval—i.e., the rate of caries attack in children, or the incidence of caries on the surfaces of their teeth—not its incidence on the population.

You also refer to claims made for this method of caries control, though it is the only method whose efficacy has been conclusively proved by repeated and rigorously controlled experiments on human material. The evaluating committee of the Michigan conference<sup>1</sup> refers to the findings as facts, not as claims and the Council on Dental Therapeutics of the American Dental Association<sup>2</sup> also regards the facts as conclusively proved. The journal of that Association has advocated

the general adoption of this technique.<sup>3</sup> The apparent reluctance of English dentists to accept this advice does not arise from any serious criticism of the validity of the American findings but from quite other reasons.

You agree with Weaver in regarding postponement of caries as distinct from real prevention, and regard a three- or five-year postponement as relatively brief. But relative to what? How long is the average life of an Englishman's tooth or set of teeth? The bulk of dental suffering in children results from caries of the temporary molars occurring in the last five years of so of their normal period of retention. Postponement of this would be real prevention. Also most permanent teeth are lost from parodontal disease, yet most dental pain results from caries. Even if one considers five years as a brief period by which to prolong enjoyment of a natural dentition, the avoidable suffering from toothache or dental treatment or both is not negligible. Surely prevention need not mean total prevention and a simple, cheap, and harmless method of partial prevention, whose limited efficacy is undoubted, does justify enthusiasm.

To wait for a universal panacea is unrealistic, and if we are to be only moderately satisfied with such a simple and certain method of partial prevention what must our attitude be to ordinary dental surgery, that most unpleasant and expensive of all methods of control? It cannot even be claimed that dentists postpone the loss of teeth from caries as much as fluorine is known to.

In finding no reference in the report to the effect of recent dietary changes you must have overlooked the remarks of Ricks<sup>4</sup> near the end of his paper. He said, "Recent post-war observations in England, Italy, India and Sweden emphasized the fact that the reduced sugar ration actually decreased the caries incidence of the population." You omit to mention what seems to me the most important conclusion of the conference, which is expressed in the evaluating committee's statement that 'studies by a number of investigators indicate that the restriction of sugar, either refined or natural, is effective in the control of dental caries.' They cite eleven references to support this statement. Dr D. A. Wallace in his keynote address to the conference stated that though carbohydrate restriction might be the best method of caries control it was not much use as a public health measure since it was not acceptable to the public.

It is paradoxical that while the Americans are too freedom-loving to apply much of their knowledge of caries control we on this side submit to having our diet planned by nutritionists who evidently lack that knowledge. The Ministry of Food's *Manual of Nutrition* favours concentrated starch and sugar foods and only refers to dental health in connexion with calcium intake, although there is practically no support for the theory that this is a factor in caries incidence. The neglect of this subject by English nutritionists is also apparent in a recent report on *Improvement of the National Diet*<sup>5</sup> by the nutrition committee of the Central Council for Health Education. I have criticized this elsewhere.<sup>6</sup>

I believe that a policy for the prevention of dental disease is long overdue and I have before suggested that a conference such as that at Michigan University might usefully be held here. By making use of British and Continental as well as American literature it could make even more positive and useful recommendations, and to a Government that might be able and willing to act on them, at least to the extent of educating the public—I am, etc.,

### Fibrositis

SIR—With great interest I read the article on fibrositis by Dr. Cyriax (July 31, p 251), which to my mind is written from a very one-sided point of view and necessarily invites criticism and many objections. The author writes that the 'existence of fibrositis is denied by most pathologists' a statement which is likely to mislead the reader. What most pathologists may and do claim is that the macroscopic and microscopic examination of the diseased muscles does not show (by methods available at present) any morbid changes. But this fact is no evidence that there was no disease during life of the patient. The statement must be objected to that "going back to first principles (taking a detailed history, making a clinical

or in industry. Dr L G NORMAN suggested that the mass testing of groups of school-children for colour vision would present a number of difficulties and advocated the establishment of centres at which full colorimetric tests might be carried out.

Pipers were also presented on atmospheric pollution, on the problem of fatigue, on electrical accidents, on job placement and analysis and indeed on every aspect of industrial health.

### Concluding Session

The concluding session was presided over by LORD WEBB JONES, who congratulated all concerned on a successful Congress and paid a tribute to the pioneers in industrial medicine. Mr G R STRAUSS M.P., Minister of Supply said that although Great Britain was perhaps not the first country to concern itself nationally with the health of the worker he believed there were few countries where so much care was taken to secure health and safety in occupation and to look after the worker when sick and nurse him back to health. ### Fibrositis

SIR—With great interest I read the article on fibrositis by Dr Cyniak (July 31, p 251) which to my mind is written from a very one-sided point of view and necessarily invites criticism and many objections. The author writes that the "existence of fibrositis is denied by most pathologists," a statement which is likely to mislead the reader. What most pathologists may and do claim is that the macroscopic and microscopic examination of the diseased muscles does not show (by methods available at present) any morbid changes. But this fact is no evidence that there was no disease during life of the patient. The statement must be objected to that "going back to first principles (taking a detailed history, making a clinical

examination, and drawing deductions on accepted lines—procedures practised by every doctor) forces upon the unprejudiced observer the conclusion that the symptoms so readily ascribed in the past to 'rheumatic fibrositis' are all in fact the result of articular lesions.

Regarding the pathology of non-articular rheumatism it must be noted that many diseases are known which at present have no pathology. Migraine (paroxysmal headache) is a very well-known malady which belongs in this category. In many cases of angina pectoris the attacks of severe heart pain are due to transient relative anaemia (hypoaemia), and are believed to be caused by a functional spasm of the blood vessels, but are independent of organic cardiovascular disease.<sup>1</sup> In gastrointestinal allergy attacks of severe abdominal pain occur, with no objective signs, which are completely relieved by adrenaline (Hurst). Severe pains in back, limbs, head, and eyeballs are a regular feature of many acute infectious virus diseases (smallpox, influenza yellow fever, etc.) In all these maladies no pathological changes are known at present to occur in the painful areas, and the assumption that an interarticular displacement is present is obviously out of the question.

I strongly object to Dr Cyriax's contention that the existence of spasm in several muscles provides a strong indication that the muscles themselves are normal, because several muscles may be and often are diseased. Nor is it correct to recommend as preconceptions to be discarded that a muscle in spasm is tender and that tenderness of muscle indicates a muscle lesion. Limitation of movements in more than one direction can and does no doubt occur if several muscles are affected.

For a proper understanding of non-articular rheumatism it is necessary to take into consideration at least two fundamental facts about muscle physiology. (1) A muscle contracting under ischaemic conditions (anoxia) gives rise to severe and agonizing pain (Sir Thomas Lewis) and (2) injection of hypertonic saline into a muscle is associated with referred pain (Lewis and Kellgren 1938). Similar clinical observations have been made and published by me.<sup>2</sup>

In 1938 I described muscular rheumatism (myalgia rheumatica) as a muscular disease localized in well definable parts of a muscle or its appendages. Several muscles may be affected (polymyalgia). The disease can be diagnosed objectively by the presence of myalgic spots, pressure on these spots elicits a severe and agonizing pain (not tenderness as described by most authors which may be present in a normal muscle). As a pathognomonic sign I described the very important fact that pressure on a myalgic spot elicits an involuntary movement by the patient—e.g., jerking of head, shoulder, etc., or the patient makes a face.<sup>3</sup> The spots, of which the patient is absolutely unaware, do not coincide with the painful skin areas complained of, which are of a referred character. The myalgic spot is harder to the touch than the surrounding area, nodules are very rarely present.

I have put forward the hypothesis that the myalgic spots are due to a local vasomotor disequilibrium, either vasoconstriction by stimulation of the sympathetic, or abnormal vasodilatation by stimulation of the vagus (vagus), which would lead to a deficient local circulation and anoxia. The theory accounts for the symptoms of myalgia and explains the fact that injection of procaine into the myalgic spots leads to a cure. The latter has been confirmed by many authors (Moynahan and Nicolson,<sup>4</sup> Kelly<sup>5</sup> and others). As a matter of fact evidence is accumulating that pain is very often a sympathetic phenomenon, produced by afferent vasoconstrictor axon reflexes from the periphery, and can be abolished by anaesthesia of the corresponding sympathetic ganglion (Leriche<sup>6</sup>).

Now Dr Cyriax contends that primary rheumatic fibrositis is an imaginary disease. The symptoms erroneously ascribed to this condition are all the result of articular disorders (largely internal derangement) at the spinal joints. This is a very one-sided assumption for which no evidence is given (x-ray findings, narrowing of an intervertebral space). That manipulative treatments help or improve some cases is certainly no proof. On the other hand, the fact that local anaesthesia of all myalgic spots leads to a cure shows conclusively that an internal derangement at the spinal joints is a theory which scientific medicine cannot accept.

It would appear that displacement of an intervertebral disk has become a fashionable diagnosis, which in the opinion of

many authorities is much too frequently diagnosed. Dr Cyriax's article may, I am afraid, make doctors take up a wrong attitude towards the patient. Either psychoneurotic pain will be diagnosed, or medical men will, influenced by the theory of a displaced intervertebral disk, subject many patients unnecessarily to the severe ordeal of laminectomy. In my opinion this operation should not be considered unless there is conclusive x-ray evidence of a prolapsed disk and myalgia has with certainty been excluded—I am, etc.,

#### Intra-abdominal Hydrocele

SIR—On reading through the *British Medical Journal* for the past year I came upon Messrs D P Burkitt's and B N Kununka's interesting description of a case of abdominal hydrocele from the Lango district of Uganda (Aug 2, 1947, p 175).

In 1935 I published an account<sup>1</sup> of two cases of this condition in the Teso district of Uganda, one of the cases being of the same (Alango) tribe as that described by Burkitt and Kununka. At this time I could only find reference to 36 previously recorded cases. Dr E V Hunter, however, told me of a case which he had also seen in the Teso country, so the disease does not appear to be very rare in endemic hydrocele districts such as the Eastern Province of Uganda.

I have made no study of any recent literature on the theories of causation. Macewen<sup>2</sup> believed that the funicular vaginal portion of the peritoneum, instead of terminating on the abdominal side at the internal ring, was carried as a sheath along the anterior aspect of the cord, "so that this funicular vaginal process of peritoneum would be continuous and patent from the testicular covering to the deepest part of the pelvic portion of the cord. When this elongated sac became distended with fluid a bilocular hydrocele would form, the constriction being made by the aperture in the abdominal muscles through which it passed."

The most probable explanation, and one which has been supported by Jacobson, Reclus, and Villeneuve, is that distension with fluid occurs in a funicular vaginal process which is patent from the scrotum up to the internal abdominal ring. The internal pressure within such a sac causes expansion into the abdomen. This is the theory which is favoured by Burkitt and Kununka—I am, etc.,

#### Lumbar Sympathectomy for Varicose Ulcers

SIR—I read with interest Mr Harold Dodd's letter (Sept 11, p 532) on this subject, and was surprised at his interpretation of my article (July 24, p 203). Unlike Dr Marcus Werquin, of Paris, I do not advocate it as a primary treatment for chronic varicose ulcers. As clearly stated in the article, "only because all non-operative and all available operative procedures had failed was sympathectomy considered", and then only because there was a vascular-stasis factor present with cyanosis which was shown to be relieved following lumbar paravertebral block.

I wish to point out that in none of these four patients was lumbar sympathectomy thought of or resorted to until it was proved in each, by reference to past surgical records, scars, and veins on their legs, that the following criteria were satisfied: namely, there had been an adequate high ligation, with division of the internal saphenous vein at the saphenous opening; division of all named and unnamed branches there, besides, when necessary, further lower multiple division and excision of this vein lower in the leg, without any healing of the ulcer. To save printing space, this procedure, which is routine in Mr Maingot's clinic at Southend, was not specifically stated in full but was implied in each case history.

I fully agree that supportive bandaging fortunately heals most varicose ulcers, but one has only to work and personally treat these patients in an out-patient varicose vein clinic,

was my duty while at Southend-on-Sea General Hospital, realize that 'some, in spite of all medical and surgical treatment, remain a chronic anti-social disability to their unfortunate owners' It was these that it was my pleasure and privilege to treat and thus far alleviate.

I agree that lumbar sympathectomy has but a small place in the treatment of ulcerated legs, but when it can be shown to heal chronic ulcerated legs where there is an associated element of cyanosis which responds to reflex vasodilatation, as did these, then it must be considered. I further believe in the importance of continuing to wear an elastic stocking after treatment to protect the skin from trauma from without, and oedema from within—I am, etc.,

Shotley Bridge Co Durham

JOHN BORRIE

### Treatment of Indolent Ulcers

SIR—The countrywoman's philosophical attitude to an indolent varicose ulcer from which she may have suffered for years is often that 'it is best not to heal it, lest the poisons be driven inward'. In the days when such ulcers were incurable it was a comforting attitude of mind although it offered little bodily comfort.

Faced with ulcers of considerable size and venerable age whose possessors refused to have their veins treated though their legs resembled a map of the Nile delta with its manifold ramifications, one was left with the problem of alleviating the pain without any possibility of putting the patient to bed owing to unending household duties and lack of help. After many experiments I find that the following is more satisfactory than anything of which I have read.

Gentian violet 1% is stirred into sulphonamide powder until it forms a creamy paste. The ulcer, previously cleaned by hot fomentations for two or three days, is now filled in with the paste level with the skin surface. The paste is allowed to dry thoroughly, which takes 15 minutes. This drying is essential, as otherwise the filling pulls away at subsequent dressings. The area is covered with a piece of well powdered gauze or lint, and the leg bandaged in the usual manner from toes to knee with crepe bandage, ichthamol paste bandages, or, if the patient's skin is tolerant, an elastic adhesive bandage in which a window is cut to facilitate weekly dressings. At the first dressing the G.V.S. (gentian violet-sulphonamide) filling usually comes away with the lint, but thereafter the discharge and seepage ceases, and at subsequent dressings the G.V.S. filling remains adherent to the ulcer and only a few cracks need touching up. The filling remains as a sterile scab under which the ulcer heals.

Pain is relieved almost completely during the first week, and in six weeks ulcers of 10 years' duration have healed without rest in bed. If the patient can rest or will have injections, ligation or other curative measures for the varicose veins, so much the better, but for the local treatment of indolent ulcer I have found nothing better, and after a two years' trial pass on the information, as the alleviation of pain is quick, marked, and pleasing to the physician and more so to the patient—I am, etc.,

ERIC PUDDY

### Use and Abuse of Tonsillectomy

SIR—The correspondence on this subject appears to be developing along the usual lines of violent antagonism and protagonism, exemplified by Mr T. B. Layton (Aug 7, p 310) and Dr A. M. Tait (Sept 11, p 534). May I suggest that, as usual, the truth lies somewhere between the two? There is little doubt that far too many tonsils and adenoids have been removed and probably still are being removed. On the other hand no general practitioner or specialist who has dealt extensively with these cases will deny the very real benefit reiterated again and again by the parents and only too obvious in the children, of the removal of truly diseased tissue. Risking accusations of facile optimism, I would suggest that the abuse is lessening and that there are several good reasons for this. Without in any way wishing to restart the guillotine-versus dissection controversy it may be said that in the heyday of the guillotine 'Ts and As' was carried out as a trivial procedure as a sideline either to general practice or to general surgery in many instances.

Since the indications and otherwise for the procedure tend to be skimped in the teaching of a crowded syllabus and are often inadequately dealt with in general textbooks it followed that however

competently the actual technique was carried out there was apt to be a lack of study and appreciation of the basic physiology and pathology of the region and conditions concerned. With crowded clinics, the "snatching" of tonsils, and over rapid discharge from hospital there has been a natural tendency for the percentage of unnecessary operations to be considerable.

Several important factors are motivating slowly against this tendency. First, the sifting of patients by general practitioners and school medical officers has, even in a limited personal experience, become more accurate. Whether this is due to a general improvement in knowledge of the subject or to belated realization of the misfortune of an unnecessary operation it is hard to say. Secondly, the gross shortage of nursing staff and therefore of beds and theatre facilities tends towards more stringent selection at hospital-clinic level. Thirdly, the general teaching and increasing use of careful surgical dissection enable the tissues to be more leisurely and accurately examined at operation and therefore a better picture of the normal and abnormal formed.

The indications and contraindications for operation are admirably discussed in several small ENT textbooks and several general volumes, and if they are accurately and deliberately applied, with an unhesitating trial of conservative measures in doubtful cases, unnecessary operation should be a rarity. As regards x-ray treatment mentioned by Dr J. H. Douglas Webster (Sept 11, p 534), I would suggest that this useful measure is in danger of disrepute through misapplication. It is the general experience, as exemplified in the literature on both sides of the Atlantic, that simple hypertrophy is *per se* very rarely an indication for operation and will usually resolve with age and conservative treatment. As in the once popular cautery of the tonsil (other than remnants) the mere diminution in the size of the infected organ, whether by scarring or by elimination of still active lymphoid tissue, tends towards the retention of buried sepsis in the crypts, from which it is no longer freely milked by the pharyngeal muscles, and to more serious toxic consequences. The very real value of irradiation in dealing with adenoid remnants and peritubal and submucosal lymphoid tissue in early cases of catarrhal deafness, recurrent otitis media and otic barotrauma is probably still insufficiently appreciated—I am, etc.

A. DAUNT BATEMAN

### Volvulus of the Caecum

SIR—Dr I. R. Stillman (July 31, p 255) reported two cases of volvulus of the caecum and referred to Mr Ralph H. Gardiner's earlier report of three cases (*British Medical Journal* 1947, 1, 83). The following are notes on a case which occurred in my practice 16 years ago.

A female patient aged 63 was seen at about 4 p.m. complaining of abdominal pain and vomiting. Her past history was given as influenza and an operation for "cancer" of the right breast 30 years previously. The present attack had started with pain in the upper abdomen accompanied by vomiting at 7 a.m. that morning. The pain was of sudden onset and very severe. The patient had had her bowels opened that morning but had passed no flatus since. Micturition was normal. On examination the patient, who was very thin, was found to have a pulse of 112 and temperature of 98.2° F (36.8° C). The abdomen was distended and a tense tumour was found in the right side. A provisional diagnosis of hydrops of the gall bladder was made.

At 7.30 p.m., under ether anaesthesia, Mr Harold C. Edwards performed a laparotomy and found a volvulus of the caecum and first 3 in. of the ascending colon, with obstruction by a band of great omentum adherent to peritoneum in the right iliac fossa. The caecum was greatly distended, its wall being the thinness of cigarette paper. Cecostomy was performed, the volvulus undone, and the band divided. A large catheter was tied into the caecum.

Recovery was complicated by abdominal distension which yielded to treatment by enemata and "pneumatisms". Some altered blood was passed by the cecostomy wound on the third day. The bowels were kept open by means of enemata, and aperients were used from the 8th day onwards. The cecostomy opening closed within 12 days. The patient is still alive and well and has had no further abdominal trouble, although she wears a belt for a ventral hernia which developed at the site of the cecostomy wound.

As in the other cases already referred to the predisposing cause of the volvulus was the presence of a caeco-colic mesentery. The omental band was probably the factor which precipitated the obstruction, the volvulus occurring as the caecum distended—I am, etc.

Parley Surrey

C. E. TAYLOR

### Trilene as an Analgesic

SIR—The problem of relieving pain in childbirth for patients attended by midwives has been a matter of very considerable concern and has received spasmodic public and medical interest for many years past. The introduction of the new Health Act serves to urge one on in an attempt to improve the lot of these patients in this particular respect, since it is likely that still fewer women will be able to obtain the services of a doctor during childbirth.

Attention has for too long been focused upon the use of gas and air, seemingly to the exclusion of other means of relief. It is no use struggling on to overcome the difficulties of gas and air, since the inherent disadvantages are insuperable. The apparatus is too bulky and heavy for it to be part of a midwife's equipment, even if featherweight cylinders were available; their capacity is limited. Midwives for whom a car is provided would be the only ones able to carry the requisite number of cylinders, but each midwife would need at least two complete outfits to ensure every patient receiving this form of analgesia. It is time, therefore, that a much more serious and balanced consideration be made of alternative means.

In trilene we have the best of such alternatives. It requires no bulky apparatus, and a 4 oz. bottle is all that need be carried apart from a small, compact inhaler. If trilene is administered through any of the recognized inhalers, and there are several, I believe it to be completely safe in the hands of any midwife, and there is no doubt that the relief it affords by way of analgesia, as distinct from anaesthesia, is equal if not superior to that of gas and air.

I have used trilene in my own practice for three years, the duration of time over which it has been administered to individual patients varying from one to six hours, using the Woodfield Davies modification of the Freedman inhaler. In hospitals with which I am connected trilene has been used for a very large number of patients, and, although one does not expect 100% success, so far as satisfactory relief of pain is concerned the opinions of these patients show that all but a very small minority received adequate relief. I have not met with a single case in which trilene has been the source of the slightest anxiety, and I believe that properly administered in a sealed inhaler in which only a certain amount can be placed it would be completely safe to allow its use by midwives after very minor instruction.

I would advocate, therefore, that the time has come when the authorities in whose hands the control of such matters lies should take active steps. The means of relief exist. They should be made available to the greatest possible number of patients and moreover their employment should be obligatory upon the part of midwives, many of whom fail to use the facilities which even at present they can command—I am, etc.,

London W 1

F NEON REYNOLDS

### Paludrine

SIR—I have read with interest the letter on the subject of paludrine from Dr E. S. Walls (July 24, p. 225), who has been using it on the West African coast near Sierra Leone with rather disappointing results.

Here in Malaya it has been used extensively, and on the whole with satisfactory results, particularly in the treatment of enlarged spleens among children. From this point of view paludrine is the most effective treatment we have so far employed, as well as being the least unpleasant to take. But as a treatment for the reduction of fever it has scarcely ever been used here owing to its frequent unreliability in the dosage originally recommended. For this purpose mepacrine is more effectual, especially when given in a double dose (0.2 g.) thrice daily until the fever declines. But this again is not as reliable for this purpose as quinine in 10 gr. (0.65 g.) doses thrice daily. The effectiveness of quinine appears to vary to some extent according to its solubility, and the bi-hydrochloride (produced by a reputable firm) is still the most reliable in reducing temperature, especially when (though only as a last resort) this is given as an intramuscular injection.

It would appear that Dr Walls has to deal with a virulent strain of malaria parasite, presumably falciparum, and also perhaps a highly infective vector. Under these circumstances it would be unwise to expect any one measure alone to be

completely effective. It is most likely, however, that other preventive measures are also being undertaken. Some of us here in Malaya are now using only two methods, which so far have given satisfaction and are not expensive: prophylactic paludrine, and the periodic indoor spraying of all living quarters with DDT or gammexane.

Fortunately, or unfortunately from the point of view of testing recent methods of malaria prevention, we have not yet had a really severe malaria season since the Japanese occupation. And that is where Dr Walls could help us greatly. In the personal prevention of malaria the trouble seems to be that there are few, if any, antimalaria drugs capable of attacking the pre-erythrocytic parasite recently demonstrated in the liver tissue. Enlargement of the liver as well as the spleen is probably an indication of multiple new infections. In some of these severely infected cases satisfactory results have followed treatment with mepacrine (0.1 g.) thrice daily for a week, followed by paludrine (0.1 g.) thrice daily for a week, and then bi-weekly mepacrine (0.1 g.) followed by bi-weekly paludrine on the alternate weeks. We do not know any reason why this should be better than paludrine alone, but it would be of great interest if Dr Walls would try this alternating treatment and compare it with a similar continuous paludrine course. An alternative course of quinine, iron, and arsenic could also be worth a trial, using quinine hydrochloride if available.

Another valuable remedy which he could employ on those under his close observation is what used to be known as 'quino plasmoquine'—a tablet containing 0.3 g. of quinine with 0.01 g. of plasmoquine. This, unfortunately, is no longer on the market, but plasmoquine is available under the name of pamaquin. When this combination is used carefully, with alkaline mixture and glucose, the results in several cases have been very satisfactory—I am, etc.,

Johore Bahru Malaya

J NORMAN DUGDALE

### Treatment of Fungus Infections

SIR—The problems associated with the diagnosis and treatment of fungus infections of the skin are many and varied, and in regard to treatment the attitude of the patient is of very considerable importance. It is my experience that if the treatment advised is to be given a reasonably fair trial it must of necessity be simple of application, time-saving, preferably odourless, and, especially in modern times, have little if any deleterious effects on clothing, bed linen, etc. In this connexion it is frequently the better educated members of the community who are the prime offenders, and none more so than medical colleagues. The average doctor has little enough time for relaxation, let alone to indulge in some complicated, time-consuming, and frequently messy treatment, and having had some personal experience of this type of thing I must candidly admit to having been a rebel in the past.

While all agree that the ideal therapeutic objective is a radical cure substantiated by microscopic and possibly cultural examinations, it will be generally admitted, especially from the patient's viewpoint, that clinical cure as judged by alleviation of signs and symptoms is eminently satisfactory.

From experience during the past five years I have found phenyl mercuric nitrate to provide the answers to many of my difficulties. In the form of a commercial preparation (ointment and powder) containing 0.05% phenyl mercuric nitrate it has served to procure the maximum number of clinical cures in the minimal space of time. A very widespread outbreak of epidermophytosis in the Durham coalfields was speedily controlled and absenteeism on account of incapacitating and painful foot rashes was reduced to infinitesimal numbers. Similar results have been noted in regard to members of football clubs in the district.

The routine method, combining prophylaxis and treatment, was as follows. Washing of the feet is followed by thorough drying and the application of ointment, and the insides of the socks or stockings are well dusted with powder. Few measures could be less time-consuming or simpler, and when the Durham miner adopted it after rebelling at the use of foot baths, malachite green, etc., it spoke volumes for its efficacy and simplicity, because he is a most discriminating individual.

Cases of tinea cruris have been treated with similar results and more recently I have had the opportunity of observing the

# 'LOREXANE' CONCENTRATE

## *The New Parasiticide for Pediculosis Capitis*

'Lorexane' Concentrate contains in solution 1% of the pure gamma isomer of benzene hexachloride (the active constituent of 'Gammexane' products), a powerful parasiticide

Diluted with four parts water, it produces a fine suspension which is highly effective against pediculosis capitis, and does not irritate or harm the scalp

A single application is sufficient to eradicate head-lice. One teaspoonful of 'Lorexane' to a tablespoonful of water is usually enough to cover the scalp

'Lorexane' Concentrate is odourless, clean, pleasant to handle and easily prepared for use

*Issued in containers of 50 c c and 500 c c*

ects in a number of cases of tinea capitis who for one or her reason presented epulatory problems, and the results have been encouraging

In the circumstances I have good reasons to recommend phenyl mercuric nitrate (0.05%) for its high potency, low toxicity, the fact that its action is unimpaired by the presence of body disintegration products, and it admirably fulfils the requirements which I have initially outlined in this letter—am, etc.,

Darlington

W GILLIES ANNAN

### Dermatomyositis

SIR,—Dr J MacD, Holmes (Sept. 11, p 511) gives an excellent picture of acute dermatomyositis with a probable etiological factor in the *Str. viridans* cultured from a muscle biopsy. Unfortunately neither his claim to be the first to isolate an organism from muscle biopsy nor his hopes that modern therapy will greatly influence the cure rate can be maintained.

Dermatomyositis was first described by Wagner<sup>1</sup> in 1863, and cases had been reported by Potain and by Marchand<sup>2</sup> before the syndrome was recognized by Wagner, Hepp, and Inverricht independently in 1887. Organisms have been found in many cases, dating back to Fraenkel<sup>3</sup> in 1894, who found a streptococcus in two cases. Fox<sup>4</sup> in 1913 claimed to have isolated a specific organism from blood culture and named it *Micrococcus polymyositis*. O'Leary and Waisman<sup>5</sup> in 1940 reviewed 10 cases seen at the Mayo Clinic and reported streptococci in five muscle cultures, diphtheroids in three, and staphylococci in one. Many other agencies have been incriminated, including carcinoma (Stertz,<sup>6</sup> Pick<sup>7</sup>) and thyrotoxicosis (Heuer<sup>8</sup>).

In view of these reports and many others not quoted for lack of space it appears that Dr Holmes provides only one more to a long list of primary causes giving rise to dermatomyositis. Treatment by penicillin or sulphonamides is likely to be effective only in cases where a sensitive primary agent is present, and unfortunately this is not commonly true.

Most of the misconceptions about dermatomyositis are due to the few cases seen by any one physician and consequent generalization upon inadequate data. An article based on the study of reports on 188 cases is in preparation which it is hoped will cast some light on this controversial subject. It is at least hoped that this letter will stimulate a search for a primary agent, rather than to subject every victim of this distressing complaint to long courses of penicillin and sulphonamides, which will usually be ineffective and add to the patient's distress—I am, etc.,

### Artificial Insemination

SIR—In the *Journal* of Sept 11 (p 523) you devote an annotation to the report on artificial insemination just issued by the Commission appointed by the Archbishop of Canterbury. One of the findings of the Commission runs as follows:

'In our view, the evils necessarily involved in artificial insemination (donor) are so grave that early consideration should be given to the framing of legislation to make the practice a criminal offence (my italics).'

This suggestion can only be described as a monstrous impertinence. I do not question the right of any Church to lay down rules for the conduct of its own members. If any person wishes to obtain what he considers to be the advantages that adherence to any particular faith brings him, he must be prepared to conform to the standards of behaviour demanded by that faith or to suffer excommunication or such other penalty as is imposed by the Church for lack of conformity. He cannot expect to eat his cake and have it. I have, therefore, no sympathy with Church members who, for example, complain because, since they are divorced persons, the Church

refuses to give its blessing to their remarriage. (The Church does not, up to the present, attempt to prevent them being married by a civil ceremony.)

But that any Church should attempt to compel citizens who do not belong to its membership or acknowledge its authority to conform to its standards of behaviour is intolerable in a free community. We inveigh against the tyranny of totalitarian States, Nazi, Fascist, or Communist. The tyranny that the Churches would exercise, if they had the power, would be no less totalitarian. It is for all thinking men and women to be ever on the watch that the Churches do not obtain such power—I am, etc.

NORMAN HAIRE

### Wives of Service Medical Officers

SIR—I was more than interested to read Lieut D R Morgan's concise account (Sept. 4, p 500) of his difficulty in attempting to get his wife out to the Far East. As a fellow sufferer, though in a country more favourably placed than he, I can sympathize. I too have met with the hard official mind which conspires against the well-being of married doctors who through no fault of their own happen to be under 25. In B A O R, even when married quarters are available and one offers to pay the passage of one's wife and family, yet one's application is refused. Because one was born too late or qualified too soon one is denied the stability possible when two married people live together. No matter that British civilians over here may bring their families out to them, and likewise any private soldier over 21 may live here with his wife. Resident families can invite their mothers, fathers, sisters, and brothers for a holiday in Germany. Yet there is some 'reason' why a young doctor may not have a quarter for his wife.

Though one could in theory qualify and practise the delicate art of medicine at the age of 21, yet the Services do not consider a doctor old enough to live with his wife until he has achieved another five years to his credit. For a country striving for security and stability in future years how farcical an attitude its leaders take towards their younger generation! How can a family begin on a stable emotional footing when they are separated for periods even so seemingly short as six months? During time of war it was often necessary for husbands in the Services to be away from their wives and families for long periods of time. The existence of the nation came before consideration of the welfare of the individual family units. Now in time of relative peace the future of the nation depends on the stability in every person's life and home. I would end by expressing my agreement with Lieut. Morgan that when separation is not necessary it is indeed criminal cruelty when enforced for no beneficial purpose. Certainly no amount of official explanation will ever make it otherwise—I am, etc.,

J H ATPED  
Lieutenant R A M C

### Fitness to Drive

SIR,—Despite all the efforts of various authorities and experts to reduce the casualties on the roads the figures are still appalling. Studies have been made by engineers, road surveyors, and other technicians. Propaganda, most of it excellent, is carried out to influence both the adult and child population, and still the terrible toll of the roads goes on. In the last analysis the human factor is the important nucleus of the problem. At present any car driver fills a form stating he is free from certain disabilities and is fit to drive. After some serious accident the driver, when found to be unfit to drive, may or may not receive some punishment for his wilful misinformation. This procedure of delayed closing of the stable doors is of little value except to satisfy punitive members of the bench. Meanwhile doctors have difficulty in finding hospital beds for other cases.

It would appear desirable that the claim of a would-be driver, that he is fit to be in charge of a lethal weapon, should be substantiated by a medical board before the accidents happen. It is of course obvious that at the present time medical men have sufficient to cope with, and a further duty of certification of this nature might be impractical at present. The matter, however, is one which merits serious consideration. A second

point arises which is the immediate purpose of this letter I have frequently examined men who are obviously a potential menace as drivers—for example, chronic anxiety states with complete lack of self-confidence, individuals who suffer from frequent black-outs and so on. Many of these are professional lorry drivers who inform me and my colleagues that they would like to give up this job but cannot afford to do so. This week I saw a man with post-traumatic personality changes and deterioration following fractured skull and subarachnoid haemorrhage who recently became a lorry driver in the hope that this would help his nerves.

Discussion with nearly a score of my colleagues who have had similar experiences resulted in agreement on two points: one that doctors examining a patient for various purposes, such as medical boards of different kinds, have no right or duty to inform any authority of their opinion on this matter, and that doctors in private practice would be violating professional confidence if they took any action from a sense of public duty; two that it would be a proper procedure to write to you to learn the views of the profession generally. In addition, it was suggested by some that perhaps this is a matter on which the Ethical Committee might well provide some guidance—I am, etc.

S SHARMAN

### Shortage of Nurses

SIR—In his letter (Sept 4, p 500) Dr N Strang states that the numbers of nurses in employment in this country are dwindling. Nothing could be further from the truth. It is estimated that there are some 29 000 more nurses and midwives in employment in Great Britain now than in 1938, and, while no strictly comparable figure for 1938 and 1948 for hospitals only is available, all the evidence seems to show that hospitals have at least kept pace with the general increase and probably done rather better than that. In March, 1948, the number of nurses and midwives employed in hospitals in Great Britain was 142 534, and the number in the public health and domiciliary services brought this to a grand total of 168 840, out of an estimated total of 189 000 nurses and midwives in all forms of employment. The increase in the numbers employed in hospitals only in the last nine months is 4 900 and the increase in the public health and domiciliary services together with the hospitals 6 100.

As regards student nurses and pupil midwives the numbers have risen from 43 300 to 52,079 if 1938 is compared with 1948, an increase of about 20%.

It is true that many more nurses and midwives are needed to meet the expanded demands for their services and to enable available beds to be opened, but it is important not to discourage recruitment by suggesting that the numbers of nurses and midwives are declining—I am, etc.,

### POINTS FROM LETTERS

#### Rutgers 612

SIR RICHARD CHRISTOPHERS, Cambridge, writes: The following information given in a letter from the Carbide and Carbon Chemical Corporation, New York, regarding the mosquito repellent Rutgers 612 may be of interest to some readers. This substance under the trade name of insect repellent 612, would appear from the letter to be solely manufactured and marketed by the above-mentioned firm and not, as stated by me in my paper on mosquito repellents in Vol 45 of the *Journal of Hygiene* by the National Carbon Company, who are no longer concerned in this respect. My statement based on information available at the time that Rutgers 612 was not a pure substance is also objected to, as it is stated to be better than 99% ethylhexanediol, probably the purest heavy tonnage industrial diol being marketed to day. Also there now seems to be no difficulty about short supply, the letter stating that the productive capacity of the firm is many times the current demand for this material. Lastly, the firm's letter states that Rutgers 612 is not, as was stated, a paint and plastic solvent and that it does not dissolve or soften rayon, nylon, and certain other plastics mentioned or nail lacquer. Rutgers 612 is a very effective insect repellent and has certain advantages which make it preferred by some to dimethyl phthalate. It is satisfactory to know that it is now apparently readily available on the market, unless there is any restriction on its import to this country.

## Obituary

J H WILLETT, MD, FRCOG

We are indebted to Mr Percy Malpas for this appreciation of the late Dr J H Willett.

The death of Dr Willett, of Liverpool, on July 13 at the age of 73 years must have stirred many memories in the minds of all who have been concerned with the development of English obstetrics and gynaecology during the last forty years, particularly the many in the North of England who were glad to have known him. Not that in the popular sense he was celebrated, though his own practice of course was big enough, but in some ways he was a unique figure. Some men's departures leave a sense of sudden loss because of their very activity, we feel perturbed that so much energy is suddenly at an end. The loss we feel for Willett's death is rather different. He was a quiet man but this very quietness based on the assurance of a long and hard experience gave those who knew him that most important of gifts, a feeling of continuity with a living tradition.

James Hayward Willett graduated in the Victoria University in 1897 and came on the staff of the Women's Hospital in 1902 and of the Liverpool Maternity Hospital in 1909 a year after he had proceeded MD. He served both hospitals until his retirement from active practice in 1935. His active life thus spanned the change Munro Kerr describes in his Fletcher Shaw Memorial Lecture. How much he linked the past with the present is shown by the date of the year he joined the North of England Obstetrical and Gynaecological Society, 1901, becoming its president in 1914 at the early age of 39.

All his life Willett was hampered by very poor eyesight, and in compensation he developed an uncanny sense of touch. To see him diagnose an obstructed labour and do, for instance, a necessary version was a great experience, though towards the end assisting him at abdominal sections proved an exciting experience. All the same, his judgment was so good and his hands so gentle that he could get away successfully with his sight-hampered technique, and although he was seemingly over-shadowed by such strong contemporaries as Briggs, Gemmell, Blair Bell, and Leith Murray his contribution to his specialty was in some ways as great as theirs. Essentially this contribution was the strong influence he exercised on his juniors. A saying of his illustrates this well. To one who was criticizing the management of some case or other, a management in the junior's eyes very much at fault, Willett would say "Were you there?" No, Sir. Then you can't judge if you were not there, you can't tell what he may have been up against.

A life as quiet as Willett's does not much lend itself to posthumous anecdote, though the incidents which occurred in the clash between him and his somewhat irascible chief and teacher, Henry Briggs, can well be imagined. Whenever the history of the Liverpool school of obstetrics is recalled Willett's name deserves a high place. There are many such men in English medicine—they make no great stir, their publications are few but so often they are the men who transmit much of the tradition.

Dr CHRISTOPHER RICHARD KEMPSTER died suddenly on Sept 7 at his home in London. Born in London in November 1869 Kempster was educated at Cavendish College, Cambridge and was a student at three London hospitals, the Westminster, King's College and the London. He qualified in 1896, and early in his career he took up the study of x rays and electrotherapeutics. He had a special interest in the use of x rays in the treatment of skin diseases and was the physician in charge of the x ray and electrotherapeutic department of St John's Hospital for Skin Diseases. He also worked at the Royal Cancer Hospital, and he was a regular contributor to the medical press on subjects connected with his special field. During the first world war he acted as a civil surgeon to the War Office, as a staff captain of the City of London National Guard and he was also the medical officer in charge of radiology at a

number of military hospitals. He lived in London throughout the recent war and continued to serve the x-ray departments of the Hampstead General Hospital and the Manor House Orthopaedic Hospital, Golders Green. Dr Kempster took a great interest in the City of London and was a very senior liveryman of the Society of Apothecaries. He was a great traveller and a very good sailor, always a popular and prominent figure in shipboard life. He was very happy in his family life, as his wife shared his interests and was always his close companion and as fond of the sea as he was. Kempster loved dining out and was a good raconteur, though bothered in recent years by the fact that his hearing was not as perfect as it had been. He will be long remembered by his colleagues and friends and by his patients, in whom he inspired the greatest confidence and in whose service he never spared himself.—R J B

Miss EUGENIE LEESON WILLIS died after a long illness on Sept 12 at the early age of 38. She received her medical education at Cambridge and at the Royal Free Hospital, obtaining the Cambridge MB in 1937, after qualifying for the Conjoint Diploma in 1935. After a period as house surgeon at her own medical school, and after other resident appointments in the South of England, Miss Willis took the English F R C S in 1939, and shortly afterwards was appointed resident surgical officer at the Oldham Royal Infirmary. From 1942 she devoted herself entirely to orthopaedic surgery, and during her short career as a specialist in this branch she did very valuable work, mainly at the Manchester Royal Infirmary. As chief assistant to the orthopaedic department there from 1942-5 she had to bear a very heavy burden in the routine care of hundreds of battle casualties which were admitted at a time when the hospital staff was severely depleted. Shortly after the end of the war she was able to turn her attention to a wider sphere of work as visiting orthopaedic surgeon to the municipal hospitals at Oldham and as orthopaedic registrar to the Manchester Babies' Hospital. Miss Willis also served the Manchester University as a teacher in the departments of anatomy and orthopaedic surgery, but what promised to be a busy and active career was gravely threatened in its earliest days by the development of the chronic disease from which she ultimately died. Her courage in facing her disability, and her determination to work despite her grave affliction earned the admiration and respect of her many friends, to whom her memory will always be vivid.

Dr JOHN ALEXANDER WATT, who retired from Derby about two years ago, died on Sept 13 at West Runton, Norfolk. Over a period of about forty-five years he led an active life which included public health work, war service, and private practice. He will be remembered chiefly, however, for his services to the British Medical Association and as a public servant on the Derbyshire County Council. In 1899 he graduated MB, ChB at Aberdeen, and in 1909 took the DPH. His first appointment was in Lanarkshire and his next in Ilkeston, Derbyshire. Dr Watt became tuberculosis officer and assistant medical officer of health for Derbyshire in 1913, and continued there until 1925 apart from the war period, when he served as a temporary captain in the R A M C with a field ambulance in France. In 1925 he entered private practice, and for twenty years held the part-time post of medical officer of health for Repton rural district. Elected a member of the British Medical Association in 1899, Dr Watt was always a regular attendant at local meetings. His chief work for the Association, however, began in 1927 as secretary to the Derbyshire Division for a period of five years which was followed by the chairmanship in 1933-4. Next year he was elected president of the Derbyshire Branch and his loyalty to the Association was exemplified by the fact that after this honour he took over the secretaryship of the Branch from 1938 until 1946 when he retired from the district. He was representative of the Division at seven annual meetings between 1922 and 1939. This record speaks for itself, but the profession locally would probably pay chief tribute to his excellent work as secretary to the local medical war committee at a time when his health was beginning to suffer. He showed wisdom, experience, and a sound business talent which enabled a committee of over-worked doctors to feel confident that their affairs were in safe hands. Dr Watt served on both the borough and the county local medical and panel committees. But he did not neglect the scientific side of his work, and was at one time president of the Derby Medical Society. In public work, outside his own profession, he was chairman of the Littleover parish council and a member of the Derbyshire County Council. In 1932 he was made a justice of the peace. He was a man of strong views, prepared to back them with good arguments, but if occasionally he did not carry the day he came to the next committee quite unruffled.

## Medical Notes in Parliament

Parliament was prorogued on Sept 13. In the Speech from the Throne which reviewed the Session, note was taken of the passage of the Act to abolish the Poor Law and to make improved provision for children deprived of a normal home life. There had also been discharged "the great task, which it has fallen to this Parliament to undertake, of giving legislative effect to a comprehensive scheme of social security. This scheme, which has now been brought into operation, will promote the health and well-being of My people, provide a substantial resource in any periods of unavoidable unemployment, and relieve those anxieties which, in the past, so often attended sickness, disability, or old age."

On the following day, Sept 14, a new Session was opened by the King. His Speech explained that Parliament was summoned for further consideration of the Bill to amend the Parliament Act, and that it was not proposed to bring forward any other business in the present Session. Debates followed in both Houses on the Address.

### Road Safety

Opening a discussion on Sept 15 Colonel HAMILTON said that during the past 22 years there had been killed on the roads of the United Kingdom about 144,800 people, a large proportion of them children. Last year had been a better year than many, but even so, on the average, 13 or more people were killed each day. An accident depended almost entirely on the speed at which the motorist travelled. Remarkable results had been achieved in some places where care had been taken about the moderation of speed. Propaganda was at present directed to keeping the victim out of the way of the lethal weapon instead of inducing the man who wielded the weapon to handle it more carefully.

Mr CALLAGHAN in reply, said the 30-mile speed limit was not a licence to drive at that pace on all occasions. The proper speed depended on the traffic and the circumstances. The way to avoid accidents was to have a free flow of traffic moving at a constant speed. Beside speed factors causing accidents were the condition of the vehicle, carelessness and selfishness of road users, and the construction of the roads. He was planning to pick out some vital aspect of road safety so that attention could be concentrated on that nationally or locally during a particular week.

## Medico-Legal

### PENSION FOR DEATH FROM CANCER\*

[FROM OUR MEDICO LEGAL CORRESPONDENT]

In recent pensions cases the view has prevailed that cancer is in the ordinary way not caused or aggravated by war service. A claimant may still, however, show special circumstances, and then the presumption in his favour which the law gives will operate and the Minister of Pensions has the burden of showing that the disease was not caused or aggravated by war service.

A gunner joined the Army in 1941 and was discharged in December, 1944, with cancer of the colon. Early in 1946 he claimed that this was aggravated by war service because it was not properly treated. The pensions appeal tribunal rejected his claim, and in August of the same year he died. His widow claimed a pension in respect of his death, and the tribunal rejected her claim also. She appealed to the High Court, and Mr Justice Denning remarked<sup>1</sup> that delay in treatment was a special circumstance in which cancer could be aggravated by war service. The gunner had had gastric symptoms for a long time during his service, but the disease had not been diagnosed or treated by any military doctor. During a brief compassionate leave in August, 1944, he had had severe abdominal pains and vomiting, and a civilian doctor had sent him to hospital, where an emergency operation was performed. The issue became a question of fact. Had he reported sick frequently with stomach trouble, as he had said? The Minister said that he had reported occasionally with ear and dental trouble, but there was no record that he had ever reported with stomach trouble except on one occasion, when he had received treatment as

<sup>1</sup>The Times June 1 1948 Lee v Minister of Pensions

skilled as any that a civilian doctor would have given him. On the contrary, the gunner's story was confirmed by his history taken down at hospital, by his captain, and by a comrade. His widow said that he had come home once for two days, being absent without leave and had said that he was sick and tired of going to the Army doctors. He had been punished for that offence by being made to dig a field, which in his own words had nearly killed him.

The judge saw no reason for taking so strong an adverse view as to disbelieve all these witnesses. It could not be said that the man's account was proved beyond reasonable doubt to be wrong. Records were not always complete, some might be lost or mislaid. The presumption in the gunner's favour was not rebutted. A specialist's opinion should have been taken long before August, 1944, and if it had been taken an earlier diagnosis might have been made and treatment given. His widow was therefore awarded a pension.

### Questions in the House

A fortnight after the hearing of this case Mr LIPSON in the House of Commons on June 15 had asked the Minister of Pensions how many applications for a pension had been refused in respect of ex-Servicemen suffering from cancer. He also asked the Minister to arrange for all these cases to be automatically reviewed in the light of the recent judicial decision.

Mr G BUCHANAN said that the number of applications from ex-Servicemen in respect of cancer which had been rejected was estimated to be about 5,500. Pensions had been granted in respect of cancer in about 1,000 cases. Mr Buchanan stated, however, that so long as he was bound by medical evidence and legal decisions he must rule out most applications for a pension in cases of cancer.

Mr CHETWYND on June 8 had previously invited the Minister of Pensions to make a statement on applications for pension in respect of cancer in view of Mr Justice Denning's judgment in the case of *Lee v Minister of Pensions*.

Mr BUCHANAN in reply noted that the appeal was allowed primarily on the grounds that an earlier diagnosis of cancer and operative treatment might have prolonged life. The reasons given by the learned judge for allowing Mrs Lee's appeal did not constitute any new approach to pension entitlement in cancer cases. Although with very rare exceptions, cancer was authoritatively held to be not caused by war service, rejection of application for pension was not automatic. All cases were examined sympathetically to see whether there was delay in diagnosis or treatment due to war service which might have hastened death. Where there had been such delay his Department did not hesitate to grant a pension.

## The Services

The Efficiency Decoration has been conferred upon Colonel H V Leigh OBE, RAMC, TA.

The Legion of Merit, Degree of Officer, has been conferred upon Colonel Frank Sheppard Gillespie late RAMC, by the President of the USA in recognition of distinguished services in the cause of the Allies.

The Decoration of Officer of the Order of Leopold II with Palm Croix de Guerre 1940 with Palm, has been conferred upon Major Frederick Alexander Edwards RAMC, by the Prince Regent of Belgium in recognition of distinguished services in the cause of the Allies.

## Universities and Colleges

### UNIVERSITY OF ABERDEEN

Harold Williams Fullerton, MD, MRCP, Lecturer in Medicine in the University of Aberdeen, has been appointed Regius Professor of Medicine in succession to Professor Robert Stevenson Aitken, MD, FRCP, who has retired.

### UNIVERSITY OF SHEFFIELD

The Right Honourable Lord Horder, GVO, MD, will deliver the opening sessional address of the Faculty of Medicine, University of Sheffield, in the Firth Hall of the University on Wednesday Oct 13 at 3 p.m. His subject will be 'The Vocation of Medicine'.

## Medical News

### Informal Dinner

At an informal dinner on Sept 14 the President and Council of the British Medical Association entertained the delegates to the British Commonwealth Medical Council. Sir Lionel Whitby, who presided, and Dr H Guy Dain both gave a warm welcome to the guests and outlined the aims and objects of the Commonwealth Medical Council. Dr A J Collins (Australia) gave some account of the work which had been done by the General Assembly of the World Medical Association at Geneva. Dr J F C Anderson (Canada) said that the medical profession in Canada was most anxious to participate in the work of the proposed Commonwealth Council. Dr A J Orenstein (South Africa) took the same view and referred to the many loyal friends of the BMA in South Africa. Dr P Moran (Eire) delighted his hearers with a brief discourse on many things. Dr C F Fernando (Ceylon) and Dr S C Sen (India) referred to the problems that would have to be faced in the future and Dr N Ahmed (Pakistan) mentioned regretfully the death of Mr Jinnah and the current disturbances in India and Pakistan. Dr T D M Stout (New Zealand) described some of the experiments with nationwide social security schemes in New Zealand and welcomed particularly the formation of the Empire Medical Advisory Bureau, a point which was also taken up by Dr J H G Robertson (Southern Rhodesia). Dr Charles Hill recalled that the Empire Medical Advisory Bureau and the British Commonwealth Medical Council both owed their inception to Sir Hugh Lett. Sir Hugh Lett described how both ideas had arisen in wartime and how during the most difficult period people in Britain were sustained and encouraged by the unwavering support of the Commonwealth. Finally an enjoyable evening was brought to a close with speeches from Dr T C Routley (Canada), who echoed Dr Anderson in promising the support of the Canadian Medical Association for the Commonwealth Council, and from Dr Alfred Cox.

### Commonwealth Travelling Professorship

Mr Arthur Sims, of New Zealand, endowed a Commonwealth Travelling Professorship under the aegis of the Royal College of Surgeons of England, the Royal College of Physicians of London, the Royal Australasian College of Physicians, and the Royal Australasian College of Surgeons. The endowment provides for the appointment annually of a Travelling Professor to visit England, Australia, New Zealand, South Africa, and Canada for the purpose of assisting in the advancement of medical science by either lecturing, teaching, investigating, or engaging in research. The Royal College of Physicians has nominated Professor G W Pickering, Professor of Medicine in the University of London, at St Mary's Hospital, as Commonwealth Travelling Professor for 1949. He will visit Australia and New Zealand in the early part of that year.

### Social Workers in Mental Health

Some aspects of the work of social workers in the mental health service are to be considered by a special committee which has been set up by the Minister of Health. Under the title of the Committee on Social Workers in the Mental Health Service the committee is "to consider and make recommendations upon questions arising in regard to the supply and demand retaining and qualifications of social workers in the mental health service. The committee is to present an interim report on these questions in relation to psychiatric social workers." The chairman of the Committee is Professor J M MacIntosh, Dean of the London School of Hygiene and Tropical Medicine, London University. The other medical members are Dr J B S Lewis, St Bernard's Mental Hospital, Middlesex; Dr R M Bates, Royal Eastern Counties Institution for the Mentally Defective; Dr R H Parry, medical officer of health, Bristol; and Dr Kenneth Soddy, medical director of the National Association for Mental Health.

### London Campaign against Diphtheria

The London County Council is intensifying its campaign against diphtheria. Since the Ministry of Health started publicity in 1940 advocating immunization striking results have been seen in London, the number of cases reported having dropped from 1,844 in 1940 to 936 in 1947, and deaths from 67 to 22. It is estimated that 75% of all London children up to the age of 13 are now immunized, the aim is to reach 100%.

### Professor J McMichael

Professor J McMichael, MD, FRCP Ed, is leaving for America on Sept 25. He is to be guest lecturer at meetings of the California Heart Association and is also giving the Musser Lecture in Tulane University, New Orleans, and the Thayer Lectures, Johns Hopkins Medical School, Baltimore. He returns to this country on Dec 7.

### Wills

Dr James Frederick Digby Willoughby, of Southwell, Notts, left £10,261. Dr Maurice Waugh Renton, of Dartford, Kent, left £14,411.

## COMING EVENTS

## King's College Hospital Medical School

The opening of the 119th session of King's College Hospital Medical School (University of London) for 1948-9 will take place at the Medical School, Denmark Hill, London, SE, on Friday, Oct 1, at 3 p.m.

## Royal Free Hospital School of Medicine

The inaugural address for the 1948-9 session of the Royal Free Hospital School of Medicine will be delivered by Mr L E C Norbury in the Beveridge Hall, Senate House, University of London, Malet Street, W.C., on Friday, Oct 1, at 3 p.m. His subject is 'The Importance of Team Work, with Special Reference to Hospital Life'. Before the address Mrs Norbury will present prizes and certificates.

## Westminster Medical School

The inaugural address will be given by Dr W T S Stallybrass, Vice Chancellor of the University of Oxford, at Westminster Medical School (17, Horseferry Road, London, SW) on Monday, Oct 4, at 3 p.m.

## International Scientific Film Congress

The second congress of the International Scientific Film Association will be held in London from Oct 4 to 11. It is being convened by the Scientific Film Association of Great Britain (34, Soho Square, London, W 1), with the help of the British Film Institute. In connexion with the congress an exhibition of illustrations and photographic material will be held at the Royal Society of Medicine (1 Wimpole Street, London, W 1) from Oct 6 to 11. The exhibition is designed to interest medical teachers.

## Charing Cross Hospital Medical School

The annual dinner of past and present students of Charing Cross Hospital Medical School will be held at the Savoy Hotel (Embankment entrance), on Thursday, Oct 7, at 7 for 7.30 p.m. The charge for dinner, exclusive of wines, is one guinea. There will be a dance in the Refectory of the Medical School following the dinner. The prize giving and inaugural address, by Field Marshal the Rt Hon Viscount Montgomery, K.G., G.C.B., D.S.O., will take place in the Council Room of the Hospital on the same day at 4 p.m. The Medical School will be open for inspection from 2 to 3.30 p.m.

## Postgraduate Lectures in Ophthalmology

A series of lectures in ophthalmology will be given in the Department of Ophthalmology of the University of Glasgow on Wednesday, Oct 6, 13, 20, and 27, at 8 p.m. Tea will be served after each paper and a discussion will follow. The meetings are open to all medical practitioners and senior students interested in the subject. Details will be published in the diary column of the *Journal* week by week.

## North West Metropolitan Regional Tuberculosis Society

A meeting of the North-West Metropolitan Regional Tuberculosis Society will be held at Colindale Hospital, London, N.W., on Wednesday, Oct 6, at 4.30 p.m., when there will be a discussion on 'The Development of the Tuberculosis Service in the North-West Metropolitan Region', to be opened by Dr H M C Macaulay, Senior Administrative Medical Officer of the region. All interested practitioners in the region are invited to attend and contribute to the discussion.

## Welsh National School of Medicine

The opening sessional address of the Welsh National School of Medicine will be given in the school on Tuesday, Oct 5, by Professor E D Adrian, O.M., F.R.S., professor of physiology in the University of Cambridge, on 'The Aims of Medicine'.

## Royal Institute of Public Health and Hygiene

A series of lectures will be given at the Royal Institute of Public Health and Hygiene, 28, Portland Place, London, W., on Wednesdays, at 3.30 p.m., from Oct 13 to Nov 24. Details will be published in the diary column week by week. Admission to the lectures is free, without ticket.

## Middlesex Hospital Medical School

The annual dinner of the Middlesex Hospital Medical School will be held at the Savoy Hotel (Victoria Embankment entrance), London W.C., on Friday, Oct 1, at 7 for 7.30 p.m.

## Royal College of Obstetricians and Gynaecologists

The Royal College of Obstetricians and Gynaecologists (58, Queen Anne Street, London, W 1), has arranged a dinner to be held at the Dorchester Hotel, Park Lane, London, W., on Friday, Oct 1, at 7 for 7.30 p.m.

## Old Students' Annual Dinner

The Westminster Hospital Old Students' annual dinner will be held at the Savoy Hotel, Strand, W.C., on Saturday, Oct 2, at 7.15 for 7.45 p.m. Sir Arnold Stott, K.B.E., F.R.C.P., will be in the chair.

## Cambridge Graduates Medical Club

The annual general meeting and dinner of the Cambridge Graduates Medical Club for 1948 will be held at Downing College, Cambridge, on Wednesday, Oct 6 at 7 for 7.30 p.m. The cost of the dinner is 30s inclusive of wines and gratuities. Those wishing to attend should send their cheque to the Cambridge Secretary Dr Windsor H Lewis, 56, Trumpington Street, Cambridge.

## SOCIETIES AND LECTURES

## Tuesday

EUGENICS SOCIETY—At Rooms of Royal Society, Burlington House, Piccadilly, W., Sept 28, 5.30 p.m. 'The Eugenics of the Utopians the Utopia of the Eugenists' by Mr Paul Bloomfield.

## Wednesday

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY 330 Gray's Inn Road, London W.C., Sept 29 10 a.m. 'The Relationship of Dental Disease to Diseases of the Throat, Nose and Ear' (illustrated by lantern slides), by Mr A C Deverell.

## Thursday

ROYAL SANITARY INSTITUTE—At Bevington Council Chamber, Sept 30, 2.30 p.m. 'Environmental and Personal Problems in Relation to Public Health' by Mr E V Crapper.

## Friday

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS—At Barnes Theatre, Royal Society of Medicine, 1, Wimpole Street, W., Oct 1, 2.15 p.m. 'On Certain Functioning Tumours of the Ovary' Biennial Anglo-American Lecture by Dr Emil Novak.

SELLY OAK HOSPITAL MEDICAL SOCIETY BIRMINGHAM—Oct 1 8 p.m. 'Recent Advances in Carcinoma of the Rectum' by Mr A Lawrence Abel.

## Saturday

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS 58 Queen Anne Street London W Oct 2 10 a.m. 'Rhesus Factor Isoimmunization and Haemolytic Disease of the Newborn' William Blair Bell Memorial Lecture by Professor Newell Willard Philpott (Montreal).

BRITISH ASSOCIATION OF ALLERGISTS—At Lecture Hall, Department of Pathology, University of Cambridge (in Tennis Court Road) Oct 2, 11 a.m. 'The Allergic Child' Opening paper by Dr G F Walker.

## BIRTHS, MARRIAGES, AND DEATHS

## BIRTHS

Barkworth—On Sept 13 1948 at Nuffield House Guy's Hospital London SE 10 Beryl (née Wright) wife of Dr F B S Barkworth of 12a Carlisle Road Eastbourne a second son—John.

Donald—On Sept 3 1948 to Mary (née Graham) M B B S wife of Patrick C Donald L D S a daughter—Patricia Mary.

Kropacz—On Sept 10 1948 at Westgate Belton Doncaster to Amy Kropacz (née Mooney) L R C P & S Ed L R F P S Glas wife of Michal Kropacz a son.

New—On Sept 16 1948 to Mary (née Nelson) wife of Dr P F J New a daughter—Stephanie Erica.

Punt—On Sept 14 1948 at Queen Charlotte's Hospital to Gwendoline (née Moore) the wife of Norman A Punt F R C S Ed D L O a son—Jonathan Arthur Gilbert.

Whitney—On Sept 9 1948 at the Lady Forrester Hospital Broseley Shropshire to Freda (née Bannister) wife of Dr R U Whitney a son—Charles Bannister.

## DEATHS

Daniel—On Sept 18 1948 at 25 Lauderdale Drive Petersham Surrey Alfred Wilson Daniel M D aged 75.

Harvey—On Sept 11 1948 at 56 Garscube Terrace Edinburgh William Frederick Harvey C I E M B C M F R C P Ed D P H F R S Ed Lieutenant Colonel I M S retired aged 75.

Hinge—On Sept 15 1948 at 11 Wood Street Woburn Sands Bedfordshire Harry Alexander Hinge C B C M G D S O M R C S L R C P Major-General R A M C retired aged 79.

Slome—On Sept 12 1948 at 79 Clifton Court London N W Irving Somerset Slome M S C M B B S.

Taylor—On Sept 12 1948 at Ashgate Cottage Chesterfield Derbyshire Vivian Johnson Morcom Taylor M Ch F R C S Ed aged 44.

Watt—On Sept 13 1948 John Alexander Watt M B Ch B D P H Aberd.

No 36

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept 4

Figures of Principal Notifiable Diseases for the week, and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland

Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever Deaths	29	3	19	—	—	36	2	34	3	1

Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	241	23	29	14	6	302	42	70	23	9
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	3 749	592	522	138	83	3 668	587	503	155	82
Live births Annual rate per 1 000 persons living	7 592	1312	935	382	239	8 464	1340	978	387	230
Stillbirths Rate per 1 000 total births (including stillborn)	210	22	37	—	—	196	35	36	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales London (administrative county) will no longer be published

‡ Includes primary form for England and Wales London (administrative county) and Northern Ireland

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales London (administrative county) are combined

|| Includes puerperal fever for England and Wales and Eire

Notifications of infectious diseases in Eire are not available this week

## EPIDEMIOLOGICAL NOTES

## Food poisoning in Faversham

An outbreak of food-poisoning with *Salmonella typhimurium* occurred between Aug 29 and 31 in Faversham and the surrounding districts in North Kent. During this period 47 cases were notified, mainly from Faversham (42), where the majority of the cases resided, and from villages and towns in the neighbourhood. There is good reason to believe that several more cases scattered over a wide area—Sittingbourne, Woolwich, Whitstable and Hither Green—occurred at the same time but were not notified either because of the slightness of the attack or because they were not recognized as cases of food poisoning at the time. The history of every one of these cases revealed one common factor—namely, that they had all attended a luncheon celebration in a London restaurant on Aug 28 at which 1,103 persons were present.

The symptoms in all the cases, varying only in severity, were abdominal pain diarrhoea, and vomiting. The onset varied in different cases from 12 hours to as much as two or three days after the luncheon. Among those who were affected three deaths occurred—all in women and all within a few days of each other between Sept 8 and 12. Only one of these cases however, has finally been ascribed directly to food poisoning by *Salmonella typhimurium*. The other two are reported to have died of natural causes—cerebral haemorrhage and cancer—after they had recovered from the clinical symptoms of food poisoning. A fourth patient, another woman, was critically ill and is now recovering. *Salmonella typhimurium* was recovered from samples of faeces in three cases and post-mortem from the large bowel, gall-bladder, and spleen in the fatal case.

Unfortunately it was found impossible to obtain any specimens of the actual food consumed at the luncheon. In the circumstances the investigations, which are being actively pursued, have necessarily been confined to the methods of preparation and storage of the various items of food at their source. It is of interest to note that the London restaurant concerned does not normally cater for such large parties and that the food provided at the luncheon, which was all cold, was procured already prepared, from different sources. The meal consisted of tinned grapefruit, cold chicken with potato mayonnaise (made, it is understood, with egg powder), Russian salad meringue and cream (synthetic), and ice cream. It is obvious that any of these items might provide a suitable pabulum under favourable conditions for the growth of *Salmonella*. An analysis of the items eaten carried out among 34 of the cases affected, including the fatal case, reveals that the majority partook of all the items provided, but that, whereas some missed one item and some another, all partook of the chicken. Most of the cases interrogated had light refreshments (tea or coffee) or a drink at different places on the way home, but no common factor could be established.

## Typhoid at Greenock

An outbreak of typhoid fever in the Greenock, Port Glasgow, and Gourock areas of Clydeside was briefly described in our issue of Sept 11 (p. 540). Further investigation in Kilcregan among persons residing in habitations beside the stream reveals the presence of a carrier. On being questioned it was found that this person, aged 80, had had typhoid fever at the age of 27 and had remained well since then. Further investigation has involved more accurate typing of the organism isolated from more than 30 cases and from the carrier. The first two results from patients have revealed the fact that the type (F<sub>2</sub>) is an unusual one. One more case has been notified in Gourock. This is a girl of 6 who appears to have been ill at home for some time before the family doctor was called in. One or two cases in this household are also under observation, and from the dates of onset it would appear that they are more likely to have arisen from the girl of 6 than from primary infection at the stream, although they too had taken part in picnics and had drunk water from the infected stream.

## Certificates of Inoculation and Vaccination

Royal Navy—Arrangements have been made under which certificates of inoculation and vaccination issued to members of the Royal Navy at home and abroad, will in future be in the international forms prescribed by the International Sanitary Conventions of 1944. Royal Navy certificates will be issued from the appropriate ship or naval establishment and will bear the official stamp. When a civilian medical practitioner who is also an Admiralty surgeon and agent issues a certificate of inoculation or vaccination other than for yellow fever the medical practitioner's signature will be authenticated by the stamp of a medical officer of the Royal Navy or of an officer of the local authority. Selected medical officers of the Royal

Navy have been authorized to carry out inoculation against yellow fever and to issue the international forms of certificate at approved centres at home and abroad. These certificates will be stamped with the official stamp of the ship or naval establishment concerned. These arrangements came into effect on May 1, 1948 but certificates previously issued should be considered valid for the periods laid down in the International Sanitary Conventions of 1944.

**British Overseas Airways Corporation**—Arrangements have been made under which certificates of inoculation and vaccination issued by medical officers of British Overseas Airways Corporation at home and abroad will be in the international forms prescribed by the International Sanitary Conventions of 1944 and will bear the official stamp of the medical department of the corporation. Medical officers of British Overseas Airways Corporation have been authorized to carry out inoculation against yellow fever at approved centres and to issue the international form of certificate. These certificates will also bear the official stamp of the medical department of the corporation. These arrangements came into effect on Sept 1, 1948, but certificates previously issued should be considered valid for the periods laid down in the International Sanitary Convention of 1944.

#### Discussion of Table

In *England and Wales* during the week there were falls in the incidence of measles 812, whooping-cough 166, scarlet fever 78, and diphtheria 18.

The largest decreases in the notifications of measles were Lancashire 140, Yorkshire West Riding 89, and Essex 76, the only increase of any size was Gloucestershire 43. The decline in whooping cough was evident only in the southern part of the country and in the south eastern counties 112 fewer cases were notified, a slight rise occurred in the north.

There were only small changes in the local returns of scarlet fever. Notifications of diphtheria were one below the total of three weeks ago, which was the lowest total ever recorded. The chief feature of the returns for diphtheria during the week was a decrease of 11 in Lancashire.

The only large return for dysentery was Lancashire 21. The heightened incidence of acute poliomyelitis was maintained. The largest centres of infection were London 7, Lancashire 7, Surrey 6, Glamorganshire 5, Staffordshire 4, and Lincolnshire 4.

In *Scotland* there were increases in the notifications of whooping-cough 26, typhoid 21, acute primary pneumonia 20 and diphtheria 12, decreases were reported for scarlet fever 16 and dysentery 14. The rise in the incidence of typhoid fever was due to the outbreak in the Greenock area to which reference is made again this week. A small increase in the notifications of diphtheria occurred in most areas.

In *Northern Ireland* there was a rise of 20 in the notifications of scarlet fever, and most areas contributed to this increase. In Belfast C B an increase of 33 in the notifications of measles was recorded.

#### Births and Deaths in Eire

The following table shows the figures for the thirteen principal towns in Eire each week from the week ending Aug 7 to Aug 21 1948. During this period there were no deaths due to dysentery, diphtheria, measles, scarlet fever, smallpox, or typhus.

Week ended	Births	Deaths		Deaths Caused By				
		All Ages	Under 1 Year	Diarrhoea and Enteritis (Under 2 Years)	Influenza	Pneumonia	Typhoid	Whooping cough
1948								
Aug 7	366	128	7	—	1	3	1	—
14	383	148	21	2	—	1	—	—
21	353	125	6	2	—	2	—	1

#### Week Ending September 11

The notifications of infectious diseases in England and Wales during the week included scarlet fever 833, whooping-cough 2 877, diphtheria 136, measles 2 608, acute pneumonia 261, cerebrospinal fever 26, acute poliomyelitis 72, dysentery 84, paratyphoid 32, and typhoid 28.

The Minister of Health has appointed Miss E. Cockayne, SRN, SCM, to be Chief Nursing Officer in succession to Dame Katherine C. Watt, DBE, RRC, who is now Chief Nursing Adviser. Miss Cockayne was formerly matron at the Royal Free Hospital.

## Any Questions?

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

#### Learning to Talk Bilingually

**Q**—What are the dangers of bringing up a child bilingually from the very start? The case is that of a baby boy of French parents living in England. He is just beginning to talk picking up some French words from his mother and some English words. When he learns a new word should he be taught both expressions at the same time? How will he be able to discern between the two languages? Is this procedure too complicated and would it produce signs of mental strain? Would it be better to start a second language at the age of say 2-3 years? The child is normal and intelligent.

**A**—If a child hears more than one language when he is learning to talk, his experiences of course are a little more complex than they would otherwise be. There appears, however, to be no evidence of any harmful results provided that the child is intelligent and, in general, is developing satisfactorily in a secure and happy home environment. If conditions are favourable the child is able to adapt to the complication of bilingual experience. The writer suggests that no attempt should be made to teach both expressions—i.e., in this case English and French words and phrases—at the same time. Learning to talk bilingually should proceed as naturally and simply as learning to talk in one language only. In time the child will discern between the two languages, responding in French to his family when they speak French to him, and in English to his English environment. If he is going to school in this country he should have every opportunity, by mixing with English children and adults, of becoming fluent in English before going to school. A third language should not be introduced until reading and spelling in both English and French are well established. The writer has known cases of backwardness in speech development in which bilingual experience in infancy and early childhood seems to have been a main factor in the retardation. These children were however, of mediocre or dull intelligence, and therefore unable to adapt themselves to the complication of a second language.

#### Calculating the Maternal Mortality Rate

**Q**—What are the criteria for calculating maternal mortality in a community? Does a death at the sixth month of pregnancy from anaemia of multiple aetiology constitute a maternal death? Is the rate calculated on live births on total viable deliveries or on total cases of pregnancy whether before or after the twenty-eighth week?

**A**—The maternal mortality rate is found by dividing the number of deaths from diseases of pregnancy, childbirth, and the puerperal state by the number of total births (live births and stillbirths combined). No correction is made for multiple births, so that the actual chance of dying from this risk is slightly understated. Every pregnant woman is exposed to the same risk of dying from causes unconnected with pregnancy as if she had not been pregnant, but in the case of some serious diseases pregnancy might be regarded as contributing to the death but not related to the immediate cause. The death in the question would be assigned to anaemia and not to maternal mortality, although this class of death is tabulated separately by the Registrar-General as deaths associated with pregnancy.

#### Heart Sounds

**Q**—What is the relationship between 'reduplicated heart sounds' third and fourth heart sounds and 'gallop rhythm'? Are they separate entities? If so how may they be distinguished clinically? What is their significance when present?

**A**—Normally there is a first and second heart sound. Any further heart sounds are numbered third and fourth. A normal third heart sound is occasionally heard, most frequently in

young children when the heart rate is slow and the child is lying on its side. Thayer believes this is due to the increased tension in the mitral valve caused by the sudden rush of blood at the beginning of diastole.

The first and second sounds are composite, each, according to Sprague and Rappaport comprising four separate entities. The first is due to vibrations set up by auricular systole, the isometric contraction phase of the ventricles, the opening of the semilunar valves, and the acceleration of blood in the great vessels during the maximum ejection phase of ventricular systole. The second sound is due to ventricular vibration during relaxation at the beginning of diastole, the closure of the semilunar valves, the vibration of the blood column and walls of the great vessels, and the opening of the mitral and tricuspid valves. Any deviation from the normal in the time relationship of the conduction of impulse, or contraction of muscle or disturbances in pressure relationship in the pulmonary or aortic systems may cause separate components of one or both sounds to be recognizable as individual entities. This may lead to a split or, if definitely separate a reduplicated heart sound or even a completely separate third or fourth heart sound. A deep breath may occasion this in a normal individual by increasing the pressure gradient between right and left ventricle and diminishing it between right ventricle and pulmonary artery. A prolonged PR interval in latent heart-block may allow the auricular contraction to be heard separately from the ventricular sounds, or in bundle branch block asynchrony of contraction of the ventricles may cause a reduplicated first sound or first and second sounds.

A gallop rhythm usually refers to an easily recognizable third heart sound in diastole when the heart rate is over 100 per minute and there are obvious signs of cardiovascular disease. It may be a protodiastolic or presystolic gallop rhythm, according to whether the third heart sound occurs in mid- or late diastole. Dock has shown that both are due to sudden tensing of the valves from rebound of the ventricle following the unusually rapid inflow which occurs when the auricular pressure is elevated. It is a sign of ventricular dilatation and impending or actual congestive failure. These added sounds can be differentiated clinically only by assessing the case as a whole and after full examination, including screening of the patient.

#### Chronic Cold Feet

**Q**—A man aged 53 has had increasingly cold feet for the past ten years. He has suffered a good deal of pain during the past three winters and now has a tender black spot the size of a pin head on each great toe. BP 150/90 pulsation in post-tibial and dorsalis pedis arteries. His general health is good and his hands are normal. Is any drug treatment worth trying? Could nicotinic acid or nicotinamide help?

**A**—The description suggests that this patient has the distal type of peripheral vascular disease in which the occlusive process is chiefly in the small vessels of the foot. The effects of treatment in such patients are often disappointing. The all-important point in management is the inculcation of the most rigid hygienic discipline in the care of the feet. Vasodilator drugs should certainly be employed. Nicotinic acid (not nicotinamide) appears to help some, and carbachol has occasionally been successful. It would be advisable to seek the opinion of a surgeon on the desirability of lumbar ganglionectomy.

#### Lupus Vulgaris and Pregnancy

**Q**—I have a patient with lupus vulgaris who has been ordered by a dermatologist to take 50 000 units of calciferol twice daily. She has now become pregnant. Is calciferol in such doses contraindicated? Is the pregnancy likely to affect the lupus vulgaris?

**A**—Pregnancy does not often have a significant effect on lupus vulgaris. In some cases the condition appears to be activated slightly but not to the extent of causing any serious anxiety. Nor does pregnancy contraindicate treatment with calciferol in the dose mentioned. However, the patient needs to be kept under close observation during treatment and regular and frequent testing of the urine and blood pressure is important. Treatment should be suspended in the presence of either albuminuria or hypertension or if the patient develops any toxic symptoms attributable to the calciferol.

Here there may be some difficulty, for common toxic symptoms such as anorexia, nausea, vomiting, and lassitude might be confused with similar symptoms associated with the pregnancy itself. Estimation of the serum calcium level might be carried out from time to time as an additional precaution.

#### Benadryl and Agranulocytosis

**Q**—Is agranulocytosis or any other dangerous blood condition likely to develop from the administration of 50 mg of benadryl three times a day for a period of six to eight weeks?

**A**—Benadryl has been used very widely since its introduction in 1946, and there has been plenty of opportunity to observe the occurrence of agranulocytosis if that was produced by taking benadryl. So far there has been no record of this and it may safely be concluded that there is no risk of a dangerous blood condition arising from the proposed treatment.

#### Stability of Calcium Chloride and Ammonium Bromide

**Q**—Are calcium chloride and ammonium bromide stable in solution? I mean a solution kept as stock for dispensing. Could you give me the approximate solubility of calcium chloride?

**A**—Both calcium chloride and ammonium bromide are perfectly stable in aqueous solution, and the usual strength for a stock solution for dispensing is 1 in 6. Calcium chloride is very deliquescent and is soluble to the extent of about one part in one and a half parts of water. Ammonium bromide has approximately the same solubility.

#### Pasta Picis Carbonis

**Q**—Tar being a carcinogenic substance is it unwise to use pasta picis carbonis (BPC) for other than brief periods? If so what would be considered a safe period of time?

**A**—The carcinogenic potency of liquor picis carbonis has recently been tested by Berenblum, whose report on this subject appears elsewhere in this issue (p 601). His earlier work was discussed in the twenty-fifth annual report of the British Empire Cancer Campaign (1947, p 133). Spectrographic analysis showed its benzpyrene content to be about 0.02%. Biological tests, consisting of twice-weekly painting of mouse skin, yielded seven tumours in 12 mice treated, of the tumours, four subsequently became malignant. While this result is properly regarded as having clinical interest, the risk of tumour induction following application of the liquor or paste in man is probably very small. It is, however, impossible to indicate any safe period, and it would be advisable for their application, especially for lengthy periods, to be subject to regular medical supervision, meantime, as Berenblum says "avoidance of long continued application of liquor picis carbonis would be a wise precaution." Berenblum's article and the general problem raised by this question are further discussed in an annotation at p 608 of this issue.

#### Correction

In the issue of Sept 4 (p 489) it was stated that a short full-time intensive course in paediatrics was given by the Royal College of Physicians of London. We understand that this is not so, and it is therefore unnecessary to address further inquiries to the College.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 25 1948

## ALLOWANCES TO MEDICAL WITNESSES IN CRIMINAL COURTS

As from Sept 13 1948, there has been a substantial improvement in the allowances payable to medical practitioners attending to give professional evidence in the criminal courts. Under the Witnesses Allowance Regulations 1948, which came into effect on that date, the maximum allowance to a witness to fact is £5 per day irrespective of whether the practitioner attends to give evidence in one or more cases, or of whether the court is in the town where the practitioner resides or elsewhere. Where, however, the time during which the witness is detained away from his practice does not exceed four hours the maximum allowance is £2 10s, except in cases where he attends to give evidence in two or more separate cases. In the latter event he may be paid allowances exceeding in the aggregate £2 10s but not exceeding £5.

This scale replaces the existing maximum rates, which are

(a) At a court in the town or place where the witness resides or practises

(1) In one case, £1 11s 6d per day

(2) In two or more cases, £3 3s per day

(b) Elsewhere, whether in two or more cases, £3 3s per day

(c) For an attendance not exceeding four hours, not more than half the above mentioned rates

The new regulations also provide for the first time for the payment of a night allowance to a professional witness where he is necessarily detained away from his home overnight for the purpose of attending court. The allowance for this purpose will be the expenses reasonably incurred by him for board and lodging, up to a maximum of £1 per night.

The travelling allowances, which remain unchanged, are as follows

(1) The third class railway fare (except where otherwise directed by the court). Where return tickets are available, the fare at the return rate only will be allowed.

(2) The fare actually paid where the witness travels by other public conveyance.

(3) Where no railway or other public conveyance is available, to a person who necessarily travels by a hired vehicle, the sum actually paid for the hire of the vehicle or an allowance at the rate of 1s 6d a mile each way, whichever is the less. (Where two persons attend from one place, the maximum of 1s 6d per mile shall apply unless the court is satisfied that the hire of two vehicles was reasonable.)

(4) A sum not exceeding 3d per mile to a person travelling on foot or by private conveyance.

The position of expert witnesses remains unchanged—i.e. they may be paid such allowances as the court considers reasonable having regard to the nature and difficulty of the case and the work involved.

In a circular which has been addressed to all courts on the subject of the new regulations the Home Secretary has expressed the hope that, as in the past, consideration will be shown to professional witnesses by informing them in advance as accurately as possible when their attendance is likely to be required.

## TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization

*Metropolitan Borough Councils*—Fulham, Hackney, Poplar  
*Non-Council Borough Councils*—Dartford, Radcliffe (limited to future appointments) Wallsend

*Urban District Councils*—Denton, Droylsden, Houghton-le-Spring, Hutton-with-Roby, Portslade, Redditch (restricted to new appointments) Tidesley

## NATIONAL HEALTH SERVICE IN SCOTLAND

The first annual conference of the Scottish Association of Executive Councils under the National Health Service was held in Edinburgh on Sept 17. Sir William M. Marshall, Motherwell, was elected president and Dr A. F. Wilkie Miller, Edinburgh, vice-president.

Sir William Marshall, according to a report in the *Scotsman* (Sept 18), reviewed the work which had been accomplished in Scotland since the start of the new scheme on July 5. He said that 92 or 93% of the Scottish people were now taking advantage of the Service. This is the figure which was given by Mr Bevan at the annual dinner of the Society of Medical Officers of Health in a speech which is reported in this issue of the *Journal* (p. 616). Sir William went on to state: "Of the doctors in Scotland 2,339 general practitioners were under agreement with the executive councils, and in the view of those in authority under 50 Scottish doctors were outside the national scheme." In July 567,000 prescriptions had been dispensed under the National Health Service, the cost amounting to 50% more than that in the same period under the old scheme in the previous year. There had also been a great demand for spectacles and in his view the cost of the Service, which had been estimated at £6½ million, was more likely to be of the order of £8 million. Sir William also mentioned the fact that in Scotland 1,080 dentists were working under the scheme and only 100 were outside it. There had been a large number of applications for dental treatment.

## Correspondence

### Pharmaceutical Services

SIR—Too little attention, I submit, has been given to Mr Bevan's speech in the House of Commons in the debate on the adjournment (*Hansard*, July 19, Column 196, *et seq.*). The real reason why Mr Bevan is not allowing the patients of doctors outside his scheme to obtain pharmaceutical services free of charge when ordered by their doctor is revealed in that debate. I transcribe the relevant passage in full.

"I should also like to make it quite clear, because there seems to be misunderstanding in some quarters about it, that if a person remains as a private patient that person will also have to pay for drugs. That of itself may have a chastening effect as time goes by. When individuals find that, having become private patients, they not only have to pay the doctor himself but have to pay the chemist's bills as well, and as that knowledge grows, it may be that the area of private practice will progressively diminish."

In an answer to me on the following day July 20, Mr Bevan gave the following pretext:

"The diagnosis of what is needed, its prescription and its provision must be treated as part of one process. I could not justify separating the prescription from the medicine in this way."

Dr Ollerenshaw rightly draws attention to the fact that pharmaceutical services have been paid for by patients not participating in the scheme. It is certainly not sufficiently realized, either by doctors or by patients, that this is so. Mr Bevan constantly repeats the statement that the Health Service is non-contributory and therefore free. He can do so only because by a political manoeuvre the contributions for the Health Service are paid into the Insurance Fund. A man and wife with two children under 18 are charged 2s 6d per week in respect of health services. This is clearly set out in the report by the Government actuary. It is to be noted, as stated in an answer (*Hansard* June 24, 1948) to me, that patients of doctors not in the Service, although deprived of pharmaceutical

benefit can claim sickness benefit on presentation of their private doctor's certificate, which need not be on the standard official form but as these forms can be obtained by applying to the executive councils a private doctor would be well advised to use them—I am, etc.,

House of Commons

## Petty Message

E GRAHAM-LITTLE

SIR—The only part of Dr W A Bourne's letter (*Journal* Aug 21 p 397) which you appear to credit with any substance in your leading article entitled 'BMA Criticized' (p 392) is what you call his 'evident sincerity'. Having heard Dr Bourne speak on more than one occasion at BMA meetings, and having read various letters of his to medical journals on the subject of the NHS, one can only wish that all our recent leaders had been endowed with the same clarity of thought and purpose. We should then as a profession present the appearance not of the amorphous mass that we do now but of the solid and disgruntled, albeit uncohesive, unit that we are in actual fact where the NHS is concerned.

As time goes on the more do we realize that we have sold our freedom not for a mess of pottage but for a petty message which, by its slighting reference to 'panel doctoring' condemned us, while at the same time it urged us to do the same thing but under very much worse conditions. When we think of all we have taken on and of the hints we have already had of disfavours yet to come, when we ponder, too, the not insignificant fact that our "wages" in the classless society envisaged for the future have not yet been settled, we can only raise our hands in helpless amazement at the ineptitude of the profession in that long drawn out and unequal contest of doctors *versus* politicians—I am, etc.,

Hove Sussex

G L DAVIES

## Compensation for Loss of Goodwill

SIR—As another who made the financial mistake of going to the war, the letters of Drs T T Hardy (*Supplement* Aug 14 p 87) and H B Porteous (Aug 28, p 96) interest me and stimulate a suggestion for reaching a more equitable share of the global sum. Our years of absence are so many years of lost increment and shrinking nucleus—for soloists, at any rate. Then take the *average* increment for the same number of years prior to service, multiply it by the number of years of absence adding an appropriate percentage for increase in fee values, and add the result to the most recent 12 months' accounting period. I imagine there are also doctors who were practising in the badly bombed areas who should be given the option of claiming similar treatment. It won't fully compensate, but will go some way towards equalization. Some such formula might be issued as a suggestion from Headquarters to the various practices compensation committees for their guidance—I am, etc.,

Salisbury

H M BOSTON

\* \* The Secretary of the Association writes: Where a practitioner is not satisfied that the normal method of calculating his compensation will adequately meet his case, he may, on submitting his claim for compensation to the Practices Compensation Committee, request that an alternative method of assessment be used in his particular case.

## What is a Specialty?

SIR—There has been a good deal of sterile discussion about the training of specialists, and now a committee is deciding how best the available specialists can be used in the NHS. But an important lacuna is being ignored inasmuch as there has been no decision about what constitutes a specialty. If in the past a man could make a living by devoting himself to a particular type of medical or surgical practice it was not long before his work became regarded as a specialty. So the ophthalmologist and the otorhinolaryngologist became two instead of one, and now the latter is beginning to split into two or perhaps even three. The cardiologist is one of the offspring of the general physician although, true enough, he may himself be an excellent all round man. Recently the neurosurgeon has sprung fully armed from the neurologist. And who would be so temerarious as to assert that no other specialties can (and perhaps should) arise, and who would be so foolish as to decide the scope of any specialty?

I write as one who for many years has practised what I recognize as being primarily a clinical specialty, with need for much laboratory investigation, which I consider part of my clinical examination. But there is a fashion, which committees may crystallize into a rule, that my specialty is a branch of pathology, and that its practitioners have many other laboratory duties but no clinical ones. I am writing this letter only to stress the need for freedom for some people to train themselves, because, their specialty being new, there is nobody else to do so. Whatever good the committee on specialists may do, let it leave flexibility of organization and personal freedom. Bernard Shaw said, 'The golden rule is that there are no golden rules'—and how often he is right!—I am, etc.,

## Free Service for Foreign Visitors

SIR,—In the *Supplement* (Sept 4, p 104) appears the statement "Visitors staying in Britain for less than two months are entitled to treatment under the National Health Service as temporary residents." Why entitled? Why should foreigners who come to Britain, say, on a sight-seeing tour be entitled to free medical attendance at the expense of the British tax payer and of the medical profession? Why should the medical profession be singled out for this imposition? To carry the matter to its logical conclusion the hotel keepers ought to be directed to give free accommodation to these visitors and the motor companies be ordered to provide cars free of charge.

Various Cabinet Ministers have stated that foreign visitors are our best source of national income. Why deliberately diminish it? The National Health Service Act is making most doctors work twice as hard as before for (as in my case) half their previous income. Why should we be required to give still more of our time and skill with no pecuniary benefit to ourselves or to the country?

I suppose now the overseas offices of our travel organizations are advertising, among other inducements to foreigners to visit Britain, free medical treatment during their two months' stay here. Positively, it would pay many of them to come here to have their appendixes removed or their chronic gastric ulcers treated—all for nothing.

My understanding of the term "temporary residents" in the Act is that they are our own fellow countrymen who have come to one's locality for a while, usually for a holiday or to convalesce, from some other town in the United Kingdom. I do not believe any medical man, when he was induced to take service under the Act, anticipated that the term would be construed (presumably by Mr Bevan) to include visitors from abroad. I do not believe that our Members of Parliament intended that the term "temporary residents" should include foreign visitors.

Has the BMA acquiesced in this imposition? If so, it is time some of us transferred our membership to a less servile organization—I am, etc.

North Lancing Sussex

CHARLES E S HARRIS

\* \* The Secretary of the Association writes: The statement published in the *Supplement* (Sept 4, p 104) represents the Ministry's view on the position of free medical services for foreign visitors. The Negotiating Committee has made representations to the Ministry on the matter, and the latter has undertaken to give further consideration to them.

## Association Notices

## PROPOSED CAITHNESS AND SUTHERLAND DIVISIONS

Notice is hereby given by the Council to all concerned of the following proposals: That a Caithness Division, comprising the area of the County of Caithness, and a Sutherland Division comprising the area of the County of Sutherland be formed in place of the existing Caithness and Sutherland Division. Any member affected by the proposal and objecting thereto is requested to write to the Secretary of the Association by Oct 23 1948, stating the objection and the ground therefor.

## PRESENT STATE OF OUR KNOWLEDGE OF THE ANATOMY OF THE PRIMATES\*

BY

F WOOD JONES, FRS, FRCS, FRACS

*Sir William Collins Professor of Human and Comparative Anatomy, Royal College of Surgeons of England*

In making any attempt to review the present position of primate anatomy it is essential that some consideration be paid to the historical background of the subject, for in no other way is it possible to appreciate the factors that have created this position or to indicate how unsatisfactory the present position actually is. A digression may be permitted in order to pave the way for what must be said concerning the phases of investigation into the comparative anatomy of the primates. Were we, following the modern fashion of testing public opinion by means of a questionnaire, to ask a generally informed set of people,

What British scientific man was the great authority on the method of formation of coral islands and reefs? the answer would probably be, "Charles Darwin." For was not Charles Darwin the propounder of the much acclaimed theory of subsidence that apparently explained so well the development and structure of coral reefs and atolls? It is quite certain that of all those who gave this answer with considerable confidence very few indeed would be acquainted with the fact that when Darwin elaborated his erroneous theory of coral-island evolution he had never seen a coral structure of any kind, even from the deck of a passing ship. Nevertheless, the publication of *Coral Reefs* in 1842 produced the very general impression that there was little or nothing that remained to be investigated regarding coral formations, since Darwin, with his painstaking researches during the voyage of the *Beagle*, had exhausted the possibilities of the subject.

Even if there might not be complete unanimity regarding the answer to the coral-island question in our imagined questionnaire, there would be general agreement regarding the second question, "Which British zoologist was the great authority on the relationship existing between men and monkeys?" The answer would inevitably be, "Charles Darwin." For was it not Charles Darwin who made it clear to the whole world that an intimate comparison of the anatomical features of man and apes guaranteed the confident assertion that man had been "evolved from an ape-like progenitor"? But most of those who gave this answer would do so entirely unaware that Darwin had no first-hand knowledge whatever of the anatomy of monkeys, apes, or men, that he was unacquainted with or ignored much readily accessible current literature on the subject and that such information as he possessed at second hand consisted largely of ill-assorted

and ill-assimilated odds and ends culled, often enough, from the writings of the anecdotal period of natural history. This is the conclusion regarding Darwin's competence to adjudicate on the relationship existing between man and apes to which any impartial reader of his works must come.

### The Malar Bone

Any comparative anatomist who reads the *Descent of Man* with an open mind can only dismiss the whole thesis as one lacking any factual basis in primate anatomy. It is remarkable that those who make confident appeal to the works of Darwin must in many cases be so unfamiliar with the actual text that such strange things as his assertions regarding the malar (jugal) bones of monkeys and man have never intruded themselves upon their notice. Of this bone Darwin writes "the malar bone, which in some of the quadrumana, and other mammals, consists of two portions. This is the condition in the two-months-old human foetus and thus it sometimes remains, through arrested development, in man when adult, more especially in the lower prognathous races" (*Descent of Man* 1st ed, vol 1, p 124). For this piece of anatomical information Darwin gives a reference to the work of Canestrini, but it is obvious to any anatomist that the account, erroneous as in any case it is, actually relates not to the malar bone at all but to the old question of the condition of the premaxilla and maxilla typical of monkeys on the one hand and of man on the other.

It is obvious that so little was Darwin acquainted with the cranial characters of the primates that he translated the whole story into the morphology of the malar bone and thereby created an anatomical absurdity with which those who so freely quote his authority appear to be wholly unacquainted. It can hardly be claimed that Darwin wrote "malar" for "premaxilla" by a mere slip of the pen, for the statement is repeated in a footnote added to the same page and again upon the page following.

On the whole the malar bone suffered considerable injustice at the hands of the Darwinians, for Thomas Henry Huxley also took unwarranted liberties with it. Huxley, who had postulated that "with the increase of our knowledge of fossil forms" the distinctions between the Perissodactyla and Artiodactyla would disappear (*Anatomy of the Vertebrated Animals*, 1871, p 292), described the post-orbital bar of the horse in the following terms: "The orbit is bounded behind by the united post-orbital processes of the frontal and the jugal" (*op cit*, p 297). This description of the horse's jugal is completely at variance

\*Read in opening a discussion in the Section of Anatomy and Anthropology at the Annual Meeting of the British Medical Association Cambridge 1948.

with the facts for the jugal does not articulate with the frontal but with the temporal. But since it is an accurate account of the bone as it is present in the cow it renders a belief that in evolution the perissodactyl and artiodactyl phyla pass one into the other" (*The Classification of Animals* 1869, p. 102) more readily acceptable.

Our knowledge of the morphology of the malar bone in the primates and the ungulates cannot be said to have been in any way clarified by the immediate propagandists of Darwinian evolution.

### Supracondyloid Foramen

Again it usually escapes the notice of those who appeal to Darwin's own statements that he asserts that the supracondyloid foramen is present "in the quadrumana and some other orders of mammals," and that in man "there is generally a trace of this passage, and it is sometimes fairly well developed (*op cit* p. 28)." This account would naturally lead the reader to suppose that in man there was generally a small foramen and sometimes a large one, and that this condition was derived from the fully developed form present in the apes. The human anatomist must realize how unwarranted such a statement is when made about the occasional presence of a supracondyloid spur in man. The comparative anatomist can only feel that by this statement Darwin smoothed away one of the anatomical facts most fatal to any belief in an evolutionary progress along the assumed line of the groups constituting the Order Primates.

As a matter of fact, no monkey or ape of the catarrhine series (with which man shows most anatomical affinity) has ever been known to develop a supracondyloid or entepitrochlear foramen, and the position is complicated by the fact that, although absent in the Catarrhini, the presence of the foramen is typical of the Platyrrhini. Of the two humeral foramina, termed by him the supracondyloid and intercondyloid, Darwin had but little real conception and no first-hand knowledge, and since in a footnote he made direct reference to the work of St. George Mivart he naturally drew upon himself the very just criticism of this authority on comparative anatomy. But this and the many other criticisms made by Mivart fell for the most part on deaf ears.

If then it must be admitted that Darwin made no contribution to our knowledge of primate anatomy and that he had in fact assimilated very little of the knowledge that was current at the time, it might be supposed that those zoologists who so strongly supported his claims had supplied the anatomical details so conspicuously lacking in his own work.

### Huxley's Contribution

In 1863, four years after the appearance of the *Origin of Species*, Thomas Henry Huxley published *Man's Place in Nature*, a book that received great acclaim from Haeckel and others and which paved the way for the *Descent of Man* eight years later. Some review of Huxley's contribution to the knowledge of primate anatomy is therefore essential. *Man's Place in Nature* is divided into three parts, between which there is but little continuity.

Part I is entitled 'The Natural History of the Man-like Apes'. It occupies 56 pages, quotes over 30 authorities, mostly of the anecdotal type, on the history, habits, and appearance of the anthropoid apes. It is a mere compilation and contains no original observations.

Part II deals with 'The Relations of Man to the Lower Animals'. It occupies 55 pages and may be said to prove what Darwin also proved—that man is an animal. But it cannot be claimed that in the 1860s this thesis stood in any need of proof. It is astonishing that Huxley should stress the fact

that both man and the dog were developed from an ovum as though it was a crucial point in testing the truth of Darwin's hypothesis. The second section of the book introduced and reiterated what Haeckel termed 'Huxley's Pithecometra thesis'. This dictum maintains that, no matter what structural feature is examined, the difference between man and the gorilla is less than that between the gorilla and the "lower primates". The Pithecometra thesis was destined to become a perfect anodyne for all those who lacked sufficient knowledge of primate anatomy to detect its fallacies.

Judged by the state of embryological knowledge at the time, Huxley's account of human development can only be described as out of date. His statement that "it is very long before the body of the young human being can be readily discriminated from that of the young puppy" can only be matched with Haeckel's claim for the late appearance of distinctive human characters in the human embryo. Haeckel's pronouncement occurs in his *Anthropogenie oder Entwicklungsgeschichte des Menschen* and is as follows: "At length in the fourth and fifth month these [distinguishing human] characters make their appearance, and during the four last months of the embryonic life of the human being, from the sixth to the ninth month of pregnancy, the human embryo is readily distinguished."

Such references as there are in this part of the book to the actual structure of man and apes deal mostly with the skeleton and are mainly metric and not descriptive.

Following Part II of the book are 6 pages, irrelevant in their content, dealing with Huxley's argument with Richard Owen concerning the hippocampus minor.

Part III is entitled "On Some Fossil Remains of Man". It occupies only 40 pages and deals mainly with the Engis and Neanderthal crania. After an examination of these crania the book ends in what appears following the previous note of high assurance, as somewhat of an anticlimax: "In conclusion, I may say, that the fossil remains of Man hitherto discovered, do not seem to me to take us appreciably nearer to that lower pithecoïd form, by the modification of which he has, probably, become what he is."

It cannot be claimed that *Man's Place in Nature* made any real contribution to the subject of primate anatomy, and Huxley is not to be ranked as a primate anatomist. Nor, as is commonly assumed, can he be regarded as the authority who supplied the facts of anatomy necessary for the full acceptance of the Darwinian hypothesis. Out of a total of some 170 papers published in his lifetime Huxley wrote only two dealing with primate structure. The only contribution he made before writing *Man's Place in Nature* concerned the brain of Ateles.

### Anatomists Contemporary with Darwin

It is naturally absurd to pass judgment upon any work unless that work has been regarded in proper perspective in relation to the background of knowledge existing at the time of its appearance. If we are to provide the background against which the anatomical knowledge of the primates that went to the making of the *Descent of Man* and *Man's Place in Nature* is to be judged we must not forget the work of Robert Bentley Todd. From 1835 to 1859 Todd issued the five volumes of his great *Cyclopaedia of Anatomy and Physiology*, and Huxley himself was a contributor to this work. Here there were available Vrolik's contribution on the anatomy of the quadrumana and Allen Thomson's account of the ovum. Vrolik gave a perfectly accurate account of the maxilla and premaxilla in the primates, and he drew attention to the fact that the entepitrochlear foramen of the humerus was present only in the platyrrhine monkeys. It seems an extraordinary thing that Darwin apparently ignored this important work so readily available to all students of human and comparative anatomy.

The fact that Darwin was only very imperfectly acquainted with primate anatomy, even at second hand, and

that Huxley's contributions added but little to fill in the gaps in Darwin's knowledge, is all the more remarkable when it is remembered that in 1863 Richard Owen was 59 years old, that St George Jackson Mivart was 36, and that the one was a master of the comparative anatomy of the vertebrates and the other a leading authority on the anatomy of the mammals and especially of the primates. But Owen had the misfortune to challenge Huxley's knowledge of primate anatomy on a point upon which his own knowledge was deficient. Owen, though the supreme authority on comparative anatomy, was defeated in a particularly stupid argument, and thereafter his weight as a critic of the ape origin of man thesis declined.

Mivart's book *Man and Apes* fell dead in 1873, two years after the publication of the *Descent of Man*. It fell dead not because the facts of primate anatomy so cogently brought forward by Mivart were proved incorrect but because they were ignored. They were ignored because a belief had been created that Darwin and Huxley had said the last word on the structural affinities between man and the rest of the primates. Unfortunately this belief persisted after the euphoria of nineteenth century scientific thought had, for many sciences, passed away. With some it seems to persist even to-day, and as a consequence the whole subject of comparative primate anatomy has failed to receive that re-examination that is so long overdue and that has already been carried out in so many other branches of science. Not until the complete anatomy of a wide series of members of the primates is recorded shall we be in a position to determine the interrelations of the different groups and to place the subject of man's place among the primates on a perfectly sound basis.

It is safe to prophesy that, as knowledge of the anatomy of the primates increases, the complexities of the problem will increase, and much work will have to be accomplished before ultimate clarity is achieved. It is satisfactory that the period of dogmatism is passing, but it will not be until anatomists regain their lost faith in the importance of morphological studies that the new era in our knowledge of primate anatomy dawns.

## CARCINOMA OF THE BREAST AND ITS TREATMENT\*

By

Sir CECIL WAKELEY, KBE, CB, DSc, FRCS  
FRSEd, FACS, FRACS

Senior Surgeon Kings College Hospital Surgeon to the  
Royal Masonic Hospital Consulting Surgeon to the  
Royal Navy

It may be thought that carcinoma of the breast is a common and hackneyed subject and one of little interest to the medical practitioner, yet it must be acknowledged that breast cancer is one of the main killing diseases in women. There can be no doubt that the incidence of this disease is steadily rising, and it behoves the medical profession to instruct and advise the public about the importance of its early diagnosis and treatment. Every year some 7,500 women die of cancer of the breast, this situation being the commonest site for cancer in women, accounting for 20% of female cancer deaths.

All clinicians will agree that the breast is a very favourable site for malignant disease, and that in early cases operative treatment gives excellent results. Even in cases

in which no treatment whatever is given the patient may be expected to live for three years, this is a fact that the medical profession does not realize.

The two common factors for causing patients to seek medical advice are pain and the presence of a lump. Only the second of these is present in early cases, this in itself is the main factor in the poor results which are obtained in the treatment of this condition.

### Spread of Mammary Cancer

Cancer of the breast begins in the acini or ducts and at first is a very limited condition, soon, however, there is spread of cancer cells up and down the ducts and then through the duct wall. From here the extension is via the lymphatics of the breast, and, lastly, via the blood stream. There can be little doubt that the condition of the stroma of the breast together with its lymphatic and blood connexions plays an important part in the spread of the disease. In girls and young women the vascularity of the breast is very pronounced, and if cancer develops the prognosis is hopeless. It is also very bad in cases of cancer developing during pregnancy and lactation, while in women over 80 the condition of the breast and its stroma is so fibrotic that the disease may last many years without any real extension. I have watched a woman aged 88 with a carcinoma of the breast for 15 years, she has refused every kind of treatment that has been advocated.

To understand the lymphatic spread of mammary cancer it is important that a true conception of the connexions of the lymphatic vessels should be forthcoming.

### The Lymphatics of the Breast

Our knowledge of the lymphatic drainage of the breast has increased during the last 40 years. As a student I often watched the late Sir Watson Cheyne perform a radical excision of the breast, divide the clavicle, and remove the supraclavicular glands. These patients rarely survived six months but died of general metastases and recurrence in the supraclavicular regions. It was thought and taught at that time (1909) that the lymphatics of the breast passed under and over the clavicle to the supraclavicular glands. It was also taught that the lymphatics of the axilla passed upwards into the supraclavicular glands. These ideas of lymphatic spread have been greatly modified during the last 20 years as the pathology of mammary cancer has been placed on a more sound foundation.

I believe, but not every surgeon will agree with me, that there is no lymphatic connexion between the breast and the supraclavicular glands except via the upper intercostal spaces and the internal mammary glands. In my opinion there is no connexion between the axilla and the supraclavicular glands. On this belief hangs the modern conception of radical mastectomy. The conservation of the clavicular head of the pectoralis major muscle implies that no lymphatic vessels pass from the breast to the supraclavicular glands in front of or behind the clavicle.

Involvement of the supraclavicular glands therefore means that intrathoracic extension of the disease has taken place and the condition is therefore inoperable.

Although the lymphatics of the breast are numerous, there are very definite pathways which determine the spread of the disease. The lymphatics from the upper and outer quadrant drain into the axillary glands. Those from the lower and outer quadrant drain for the most part into the axilla, but a few may drain to the lymphatics of the abdominal wall to the umbilicus and so via the ligamentum teres to the liver. The lymphatics of the inner quadrants of the breast drain via the intercostal spaces into the

\*Read in opening a discussion on in the Section of Surgery at the Annual Meeting of the British Medical Association, Cambridge, 1948.

internal mammary glands and the anterior mediastinum and so into the supraclavicular glands (Fig 1)

Some lymphatics may pass across the middle line to the opposite breast, while a few may pass to the parmammary glands and to the abdominal lymphatics

FIG 1—Drawing showing the lymphatic drainage of the breast

### Early Diagnosis

It is essential that early diagnosis should be made if better results are to be obtained in the treatment of carcinoma of the breast. There are several factors which have in the past prevented early diagnosis and these should be entirely eliminated to-day. The patient who discovers a lump in her breast often decides to tell no one, as it might be cancer and she might die as some of her friends or relatives have done. This fear of cancer is very real and must be tackled by the profession on proper lines. The laity must be convinced that cancer of the breast can be cured in the early stages of the disease. I have found that the average time taken by my patients before they report the presence of a lump in the breast is six months, while in some cases it is double that time. Another factor is the treatment of carcinoma of the breast by quacks and herbalists and the like. This is a free country and patients may seek advice from anyone, but it is a pity that some sort of propaganda should not be used to reveal the real danger to which the public at large are subjected.

Early diagnosis by the practitioner has in the past been hampered by the fact that nearly every textbook on surgery reveals the late stages of the disease as diagnostic factors of importance. It must be acknowledged that there is only one early sign of carcinoma of the breast and that is the presence of a lump. This lump is in the substance of the breast, is usually hard, and can often be felt by the flat of the hand. Cancer is the commonest cause of a lump in the breast, and this must not be forgotten. The lump is closely united to, if not absolutely incorporated with, the breast substance and on careful digital examination its

margin is quite indefinite. In the early stages it is entirely distinct from the skin, which moves freely over its surface, but as growth proceeds the stroma contracts and, by dragging on the suspensory ligaments of Cooper passing from the glandular substance to the skin, the latter structure becomes more or less fixed, and hence, on attempting to move it upon the tumour, an appearance of dimpling results.

In investigating any case of a lump in the breast the practitioner must never arrive at a hasty conclusion, but give an opinion of its nature only after careful and detailed examination. Thus, the age and previous history of the patient and the family history should be considered. Simple tumours generally arise at an earlier date than the malignant, while sarcomata usually affect younger individuals than carcinomata. There can be little doubt, moreover, about the occasional tendency of tumours to run in families. The length of time for which the swelling has been observed, and whether or not it varies in size at the menstrual periods, should be ascertained. The general appearance of the patient should be noted, and also the fact whether local or neuralgic pain is experienced. It is not unusual for pain to be referred to that part of the shoulder supplied by the posterior division of the second intercostal nerve, the anterior branch of which goes to the breast.

A careful inspection of the organ should be made with the patient sitting and lying down, comparing it with the opposite breast so that any signs of asymmetry may be noted. Dimpling of the skin, projection of the tumour or of the whole gland, and the situation and condition of the nipple are the chief points to which the practitioner's attention should be directed. Examination with the flat of the hand, accompanied by gentle pressure of the finger tips, must then be undertaken, it is not enough to pick up the breast substance between the fingers, as thereby false impressions are obtained.

The relation of the tumour to the gland, its shape, its consistency, whether fluctuating or not, its mobility on superficial, deep, and surrounding parts should be investigated. To this end the breast must also be examined with the patient's hand pressed to the hip, so as to put the fibres of the pectoralis major muscle into action; transverse movement of the organ across the fibres is always possible unless the growth is fixed to the thoracic wall; movement in the direction of the fibres is at once limited if the tumour has invaded the muscle or even if the overlying fascia is seriously involved. Finally, the lymphatic glands in the axilla, the supraclavicular glands, and the opposite breast and axilla must be carefully examined. After such a detailed examination, if the practitioner is still in doubt about the nature of a tumour of the breast then local excision of the whole lump and not part of it should be undertaken and a histological examination of the tissue removed should be made. If the condition is benign, then the patient will be completely satisfied and relieved, if on the other hand the condition is malignant, adequate treatment can be forthcoming.

It is important to classify the clinical manifestations of carcinoma of the breast before any decision is made about the form of treatment. The clinical classification can be divided into the following stages:

*Stage I*—Tumour of the breast only

*Stage II*—Tumour of the breast and skin changes and/or axillary glands

*Stage III*—Tumour of the breast and supraclavicular gland or glands in opposite axilla, and/or fixation of the breast to the pectoral fascia

*Stage IV*—Skeletal and visceral metastases

### Treatment

The surgeon to-day has the choice of radical surgery alone or combined with radiotherapy, local excision and radiotherapy or radiotherapy alone. After thirty years' experience during which I have operated upon over 500 women and nine men for this condition my ideas have become definitely crystallized.

**Stage I**—I am convinced that in these cases radical mastectomy is the method of choice and offers the best chance of eradicating the disease completely. However, in those cases in which the woman is slight, the breast is small, and the tumour is in the inner quadrants I perform a local excision of the breast and follow this with radiotherapy. Cancer of the breast occurring in the inner quadrants is apt to extend into the intercostal spaces without any clinical evidence whatever, and this is why the prognosis is bad in these cases. A radical amputation in a small woman with a small breast would involve extensive skin grafting of the chest wall to close the defect left behind after the amputation and this in itself would delay any post-operative radiotherapy. It has been said that radical amputation is a mutilating operation but so is local excision, and from the patient's point of view the psychological effect is better for they realize that everything has been removed and are much happier.

The operative mortality from radical mastectomy is not more than 1%, and this is due to the rare case of embolism or the very occasional anaesthetic death. With careful pre-operative preparation and the use of blood transfusion in selected cases the mortality could easily be lowered. I am not in favour of post-operative x-ray therapy in Stage I cases. I employed it for some 10 years and found from my follow-up that the results did not justify its use. There can be no doubt that x-ray treatment does produce some anaemia, and some fibrosis of the lungs always follows its application. In my follow-up I have obtained an 81% five year cure and a 65% ten-year cure. Of course it is quite fallacious to talk about cures in carcinoma of the breast, as I have had 12 cases in which recurrence took place 10 years after operation, the longest being that of a woman who died of recurrence 22 years after radical mastectomy.

**Stage II**—These cases give poor results with surgery alone, and in my series I can record only a 25% five-year survival rate. This is distressing, as Stage II cases so often form the greater proportion of cases seen in our hospitals at the present time. It behoves us to take stock of our results and to consider in what way they can be improved. Stage II cases mean lymphatic extension beyond the confines of the breast, and this being so pre-operative x-ray treatment should be given to eliminate the lymphatic vessels which are loaded with cancer cells. Pre-operative irradiation means a delay in removal of the breast for some two months, but the surgeon can arrange his cases so that irradiation is given immediately after the patient is seen for the first time and the date of admission can be fixed. In quite a number of cases the primary tumour becomes smaller, also the axillary glands, and the risks of dissemination are considerably reduced. Why, then, it may be asked, should not x-ray therapy be given and no operative measures be undertaken? The answer to this question is that the results are not as good as when pre-operative x-ray therapy is followed by radical mastectomy. Post-operative irradiation should be reserved for those cases in which there is recurrence.

**Stage III**—Surgery can be of little avail in these cases, as the condition is essentially inoperable. X-ray therapy is the treatment of choice. The surgeon may be asked to remove a fungating tumour so as to make the life of the patient more tolerable or as an ancillary to the x-ray therapy. It is curious to note that some of the worst cases survive the five year period when the prognosis from the start of treatment seemed hopeless.

**Stage IV**—These cases are the bane of the practitioner's life, for there is little that can be done for them. Irradiation is only palliative but may be useful in controlling some bone metastases and giving some relief from pain. It may well be that the extended use of endocrines in Stage IV cases will prove of real value. I have been impressed with the value of testosterone in large doses (1,000 mg.) in these cases and I consider

that it gives results comparable to those obtained by stilboestrol in cases of carcinoma of the prostate. The use of testosterone should have a much more extended trial in these advanced cases. I know of no more difficult and trying surgical case than that of advanced mammary cancer. It is useless for the practitioner or surgeon to say that nothing else can be done, for the relatives will immediately fly off to some quack, who will promise a cure with some highly coloured injection of excessive cost which must be given at a certain time each day. Such treatments go on for at least a year. When the patient dies the relatives are told that if only the patient had come for treatment a little sooner a cure would have resulted. We are all familiar with such cases and they do not do the profession any good. I therefore advise the extended use of testosterone for these patients. Human nature demands some treatment in the advanced mammary cancer case, and therefore let us as medical men and women see to it that the treatment given has a scientific basis.

### Radiotherapy

The question of radium or x-ray treatment in mammary cancer is one that has interested surgeons for several years, and I am quite definite in my sole advocacy for x-ray therapy with or without surgery rather than radium therapy. My reasons are that, although radium has been used in Stage II cases with some success, the primary tumour still persists in the breast, although it may simply be composed of a mass of hard fibrous tissue. This in itself has a bad psychological effect on the patient, because she imagines that the growth still persists and that it may eventually spread. I have often been asked to excise such a mass several years after radium treatment, and I realize the peace of mind removal of the mass brings to the patient. Radium is more local in its action than x-rays, and the outlying lymphatic vessels are more likely to come within the barrage of the x-ray tube than the radium needles.

It is essential to keep an eye on the patient's blood picture during the time she is undergoing x-ray therapy, and should this show a reduction in the red cells steps must be taken to bring the blood picture back to normal. As a rule a good iron tonic with a liberal amount of vitamins will effect this.

### Radical Mastectomy

Although it is some 50 years since Halsted advocated his radical operation for carcinoma of the breast, this treatment is still performed to-day. Yet there are certain details that I consider worth while bringing to your notice. It is important to conserve the clavicular head of the pectoralis major muscle, as this protects the axillary vessels and prevents the skin from becoming adherent to them. I have twice seen this distressing condition in cases in which the whole of the muscle was excised. Also, in my opinion, oedema of the arm is more likely to follow, as the lymphatics are compressed by the skin crossing the axillary vessels and nerves. I have never seen or heard of a patient who developed a secondary deposit in the clavicular portion of the pectoralis major, nor do I believe that there is any lymphatic connexion between the breast and the supraclavicular glands except via the mediastinum.

In dissection of the axilla it is most important to remove all fat and glands below and to the inner side of the axillary vein. On no account should any attempt be made to remove fat from the axillary artery or brachial nerve cords, because after such a course is adopted brachial neuralgia is very likely to ensue. In my student days it was a common procedure for the surgeon to display the axillary vessels and brachial plexus and remove every particle of fat from the axilla, and a large number of these cases developed brachial neuralgia which caused much pain and misery.

The radical operation itself should be definitely planned and the patient should be in hospital several days before operation. To day there is too great a tendency for the patient to arrive in hospital late one day and to be operated upon the next. This cannot be condemned too strongly, it leaves no time for any pre-operative examination, blood count, or x-ray picture of the chest to see if any secondary deposits have developed.

The technique that I use is as follows

#### Operative Technique

Previous to operation the axilla should be shaved and the skin purified over an extensive area including the back. The patient then lies on the back with the head directed towards the opposite side and the arm raised and held to a little more than a right angle. The field of the operation is protected from the patient's face and the anaesthetist by sterile towels. The incisions employed vary with the size and position of the tumour. The primary object is to remove the growth, together with the whole gland and all its accessible lymphatic connexions: the question of being able to close the wound subsequently is of secondary importance. As a rule sufficiently wide undercutting will allow very extensive wounds to be closed, but when this is impossible skin grafting can be adopted, and no lengthy convalescence need ensue.

In planning the incision the growth should be taken as the centre of a circle with a diameter 4 to 5 in (10 to 12.5 cm). It is convenient to prolong the upper and lower portions upwards towards the axilla and downwards towards the epigastrium so as to secure a straight line for the final suture (Fig 2). The upper incision is prolonged towards the axilla, and runs up and curves down towards the insertion of the pectoralis major to the humerus.

The dissection of the axilla is started first in order to avoid an unnecessarily prolonged exposure of the chest wall. The skin flaps are undercut and retracted, a transverse incision in the fascia at the level of the insertion of the pectoralis major

scapularis. The subscapular nerves are identified and protected and some branches of the subscapular vessels will need ligation. The serratus magnus can then be denuded of the overlying fascia, care being taken to secure branches of the intercostals.

FIG 3—Division of the pectoralis minor muscle

is made, the cephalic vein identified, and the anterior border of the latissimus dorsi exposed. The upper, lower, and lateral limits of the axillary dissection are thus identified. The costo-sternal portion of the pectoralis major is divided close to its insertion and retracted inwards (Fig 3). The axillary fascia is incised so as to expose the axillary vein and the dissection is then carried upwards and inwards towards the clavicle. The interval between the two parts of the pectoralis major is opened up and the costo-sternal portion retracted downwards thus exposing the pectoralis minor muscle. By retracting the clavicular head of the pectoralis major upwards the insertion of the pectoralis minor into the coracoid process can be seen. It is important to divide the tendon of the minor pectoral muscle close to the bone as no vessels are cut and no bleeding takes place. The two pectoral muscles are then retracted downwards and the axillary fat and lymphatics can be dissected away from the axillary vein. Care is taken to identify and preserve the nerve to the latissimus dorsi and the nerve of Bell, both of which are exposed in the posterior part of the wound. Hot saline packs are placed in the axillary wound

FIG 2—Skin incision for removal of the breast in cases of carcinoma

and divided close to the bone. It is important to divide the tendon of the minor pectoral muscle close to the bone as no vessels are cut and no bleeding takes place. The two pectoral muscles are then retracted downwards and the axillary fat and lymphatics can be dissected away from the axillary vein. Care is taken to identify and preserve the nerve to the latissimus dorsi and the nerve of Bell, both of which are exposed in the posterior part of the wound. Hot saline packs are placed in the axillary wound.

The lateral flap is then undercut and the whole breast and axillary contents are drawn over towards the middle line, the dissection is carried forwards and inwards, starting from the outer border of the latissimus dorsi. The inner aspect of this muscle is cleared as well as the axillary surface of the sub

scapularis. The after treatment consists in making the patient perform deep breathing exercises each day to prevent any pulmonary complications. The patient can often get up for a few hours on the third post-operative day. Early rehabilitation is tant in these cases and prevents the occurrence of thrombosis and pulmonary embolism.

#### Mammary Carcinoma in the Male

Although cancer of the breast in the male is about a hundred times less common than in the female, even surgeon is faced with these cases. In 30 years of surgical practice I have met with it nine times, and in every case

the patient had been a keen boxer in his youth. It seems to me that trauma may play a more important part in the causation of carcinoma of the breast in the male than is usually thought. In my series of nine cases the ages ranged

FIG 4—The operation area after removal of the breast for carcinoma

from 36 to 56 years: two were officers in the Navy, two were officers in Commando units in the Army, three were in the Police Force, and two were naval petty officers.

The prognosis of cancer in the male breast is very poor, the small undeveloped breast allows early lymphatic spread before the condition is diagnosed. In all my cases axillary lymphatic glands were present, and in the four cases in which I performed a radical excision the glands were infiltrated with growth. In my series of nine cases the average duration of life after operation was 30 months, all the cases dying of mediastinal metastases.

My experience of these cases has taught me that the correct treatment should be excision of the breast with the tumour, followed by x-ray treatment. But even when this has been done the prognosis is very poor in comparison with carcinoma of the breast in the female.

#### Results of Treatment

It must be acknowledged that in the main the results of treatment of mammary cancer are poor. The prime factor is the delay of the patient in coming for treatment, and this can be improved only by a definite line of propaganda. The Ministry of Health should take steps to improve this situation.

The second factor is inadequate treatment. I would like to associate myself with my friend Sir Stanford Cade, who has stressed so often the fact that the commonest error in treatment is to underestimate the extent of the disease and under-operate or under-irradiate.

One of the biggest problems which faces the profession to-day is the standardization of deep x-ray therapy. At the present time x-ray therapy varies in different centres and

in different hospitals. How can we compare results under these conditions? Confidence is an important factor in everyone's life, and the surgeon's confidence in the radio-therapeutic treatment is a weighty one. How can some surgeons be satisfied if they have no trust in the x-ray therapy equipment in their hospitals or centres? To my mind the standardization of good x-ray therapy establishments throughout the country is long overdue, and the lack of it is in no small way responsible for the poor results of x-ray therapy in mammary cancer.

Those hospitals that are fortunate enough to possess modern high-voltage plants get better results and give confidence to the surgeons attached to them. If a surgeon or practitioner has no confidence in his hospital x-ray therapy unit how can he be expected to advise his patients to undergo treatment? To my mind under-irradiation is often worse than no therapy at all.

Can we hope to have a better service under the National Health Service, or will the practitioner, surgeon, and patient be overwhelmed with the forms to fill in, red tape, and inefficiency which characterize the other services that have been nationalized during the last three years? It will be the duty of the medical profession to try to correct this tendency as soon as possible.

## EARLY DIAGNOSIS AND TREATMENT OF CARCINOMA OF THE BREAST\*

BY

VICTOR RIDDELL, MD, FRCS

Surgeon to St George's Hospital

Cancer of the breast is responsible for the death of more than 7,000 women a year in England and Wales alone, and this figure is rising rather than falling. Two-thirds (67%) of the patients operated upon in this series of 170 radical mastectomies already had metastases in the axillary glands. The main reason for this state of affairs is delay, by the patient, by the general practitioner, by the consultant, and by the hospital.

To avoid the errors responsible for delay by the profession the following vital considerations should be borne in mind.

1 *The Fallibility of Clinical Diagnosis*—However experienced we are, we cannot differentiate with certainty on clinical grounds alone between the non-malignant and the early malignant swelling. If exploration is not adopted as a guiding principle many a patient with early carcinoma will be placed upon the waiting list as suffering from a non-malignant condition, and all hope of cure may have been cast away.

2 *The Fatal Period of Observation*—A period of observation is no longer justifiable in the treatment of the doubtful breast lesion. Exploration of the swelling is the only proper procedure if there is the slightest uncertainty.

The practice in some hospitals when a patient is suspected of carcinoma of the breast is for her name to be placed upon a general waiting list to await her turn for a vacant bed. This procedure must be wrong. By such an arrangement the "carcinoma" patient may wait a varying number of weeks while others with non-urgent, non-malignant conditions are admitted in rotation. The names of all cancer patients should be placed upon a special waiting list and arrangements should be made to admit doubtful or early cases immediately. The exploration of a swelling in the breast is an emergency operation.

\*Extracts from a Hunterian Lecture delivered at the Royal College of Surgeons of England on Feb 9, 1948.

FIG 1a—Carcinoma of the right breast b Carcinoma of left breast with the arms in the position for palpation. The outstanding impression on inspection is normality. The configuration of each breast is normal, there is no elevation of the nipple and no attachment to the skin. In each case the only sign of carcinoma was a small hard lump in the breast. The axillary nodes were not palpable clinically, but in both patients metastases were found in the nodes after the operation.

### Early Diagnosis

In established carcinoma mammae there may be no deformity of the breast. In early carcinoma mammae there is no deformity of the breast—that is, there is no visible evidence of malignancy. All the cardinal signs of cancer are absent save one—a hard lump, normality is the outstanding visual impression of the breast, which is normal in form and outline and which has normal nipple and normal skin (Figs 1a and 1b). The following might be taken as working rules.

**General**—(1) A swelling in the breast of a woman of any age is cancer until it is proved otherwise. (2) It is impossible by clinical methods alone to make or to exclude a diagnosis of early cancer. (3) When in doubt, a period of observation is unjustifiable. An exploration must be carried out and the tissue removed sent for section.

**Clinical Features**—(1) On inspection the configuration of the breast is normal in early carcinoma (Figs 1a and 1b). (2) On palpation a hard lump in the breast, unattached to the skin, is the earliest sign of carcinoma. (3) The "cardinal signs"—adherence to the skin, a retracted nipple, and palpable axillary glands—are the signs of long-standing advanced carcinoma. (4) The inaccuracy of the clinical findings is greatest in the stout patient, in whom fat conceals from palpation both the tumour and the glands. Beware the ample bosom. (5) The urgency for investigation is greatest in those patients in whom the cardinal signs are absent and the diagnosis is uncertain, because it is with these patients that the chances of cure are highest.

### Clinical Examination

The breast itself should be examined with the patient stripped to the waist and with both hands clasped behind the neck. This position (Fig 1b) tenses the breast on the chest wall and by giving it a firmer bed renders palpation more reliable than when the arms are hanging by the side. Examination of the supraclavicular fossae is best made from behind, with the shoulders raised and hunched forward so as to make hollows on either side (Fig 2).

Just as negative axillary findings may lead to postponement and delay, so may non-adherence to skin. Yet it is in these cases that the best results can be expected from

FIG 2—The position for examination of the supraclavicular fossae.

radical surgery. The urgency is further underlined by the fact that more than half of the "unattached" cancers have already metastasized to the axillary nodes (Table I). No case is as early as it seems.

In those instances in which the decision is difficult or in which the lump appears to be unattached it is worth while to ask the patient to raise her arm straight above her head. In a proportion of cases a dimple will appear over the affected area of the breast and in others adherence will become obvious on gentle manipulation.

The fact that the axillary glands are not palpable unfortunately does not always mean that they have not been invaded. It is important to bear this in mind or a false clinical interpretation of the state of these glands may be made. Table II shows that whereas the

clinical error in the case of the palpable glands is small *though not insignificant* (21% of free of metastases) the clinical error in the case of the impalpable glands is 50%. This fifty-fifty chance that the disease has spread to the axilla, even though the glands are impalpable, further emphasizes the urgency for immediate treatment.

Not uncommonly the first glands to become enlarged lie on the chest wall behind the anterior axillary fold upon the

TABLE I—Frequency of Attachment of Tumour to Skin in 170 Patients

	Glands Invaded	Glands Free
Tumour attached to skin (74%)	72%	28%
Tumour unattached to skin (26%)	51%	49%

TABLE II—The Impalpable Gland and the Clinical Error in 170 Patients

	Glands Invaded	Glands Free
Clinically palpable (61%)	79%	21%
Clinically impalpable (39%)	50%	50%

second and third intercostal spaces (Fig 3). The examiner who feels only high in the axilla regularly misses these glands. As the hand is withdrawn the fingers should be pressed against the chest wall until well below the level of the axillary outlet.

Before proceeding either to mastectomy or to a course of x-ray treatment it is essential that palpable secondary deposits in the abdomen and pelvis should be excluded by clinical examination and the chest, spine, and pelvis should be examined radiologically. It is only in this way that a silent pleural effusion or symptomless secondary deposit in a lung can be discovered.

The adjective "scirrhus" suggests for some a benevolent quality. In the series under review the histological section was described in 39% of the cases as being a "typical scirrhus carcinoma." Yet in 64% of these patients metastatic deposits were already present in the axillary glands at the time of operation. A "scirrhus" carcinoma of the breast can be and often is highly malignant and may run a rapid course.

FIG 3—'Axillary' glands on the chest wall.

Clinically, cases would seem to fall into one of the following broad categories

- Stage I—Tumour only
- Stage II—Tumour and mobile axillary nodes
- Stage III—Disease advanced with local metastases
- Stage IV—Disease advanced, with distant metastases

#### Treatment\*

Treatment is a radio-surgical problem, and the parts to be played by x rays and by surgery must be taken into consideration before embarking upon either. This can only be done effectively if surgeon and radiotherapist see and discuss the case together. The answers to the following questions are helpful in deciding the order of treatment and the extent of the operation

1 Is the breast condition operable or inoperable? The answer to this question will place the case in the first two or the last two clinical stages of the disease, and by so doing will rule out radical surgery in a proportion of patients

2 Is the breast (and tumour) removable with or without leaving a defect between the edges of the skin flaps? The answer to this question will give a general indication of whether the initial treatment should be by radiotherapy or by surgery (see below)

3 Is the case potentially early or potentially late in the operable group? The answer to this question will give a general indication of whether the surgical treatment should be by radical or by simple mastectomy. A combination of adverse factors will suggest conservative surgery (see below)

X-ray therapy is still in the process of evolution, and the relative merits of the different irradiation techniques are undecided. There are still some who believe that x rays only do harm or at least do no good. Results of cases treated in the ten years before the war showed no clear advantage to be gained from using x rays, and in some series (post-operative) they actually appeared to be a disadvantage (Truscott, 1947, Haagensen and Stout, 1942, Kraemer, 1940)

The poor results were due to a number of factors which no longer obtain, such as inadequate treatment from failure to push therapy to the limit of biological reaction, inefficient apparatus, and haphazard technique. These faults have now been corrected, and the value of x-ray treatment has been clearly demonstrated (Adair, 1943, Marshall and Hare, 1947, Richards, 1948)

#### Post-operative X-ray Treatment

Post-operative irradiation is given with the intention of destroying any islets of active cancer cells which may still remain in the field of operation after the primary tumour and the glands have been removed. Ideally the course should be started as soon as the wound is healed, which is likely to be any time after the tenth post-operative day. The method has certain limitations. The dosage is too often dictated by the skin tolerance of the patient rather than by the optimum which is destructive of tumour cells remaining in the operation area, and more often than not there is serious post-operative delay in initiating therapy because of failure of the wound to heal by first intention. Rightly or wrongly these disadvantages have recently given a boost to pre-operative x-ray treatment

Many surgeons exclude their gland-free cases from x-ray treatment. They prefer to reserve post-operative irradiation for the treatment of recurrences. This implies that all the axillary glands removed have been sectioned, which is certainly desirable, but it does not always happen. The only safe procedure is to arrange for all patients to have x-ray treatment unless it is contraindicated

\*In this survey only treatment by x rays and surgery is discussed

#### Pre-operative X-ray Treatment

Pre-operative irradiation is given with the intention of sterilizing or restraining the activity of the tumour and the glands. I think it has the following advantages—at least on theoretical grounds. (1) Pre-operative irradiation is more reliable in that there is no delay (except administrative) in starting the treatment, whereas post-operative irradiation may be long delayed by some complication of the operation, such as flap necrosis. (2) If x-ray treatment precedes operation any cells which may subsequently be disseminated may be either dead or so devitalized that they are not harmful. (3) It is probable that the skin will tolerate a slightly heavier dose of x rays if its blood supply has not been disturbed by previous operative trauma.

There are certain difficulties with pre-operative irradiation. (1) A diagnosis of cancer is required before submitting a patient to a course of x-ray treatment. This information is automatically available with post-operative cases—not so with the pre-operative. (2) There is delay before the patient is able to undergo operation. This wait is very irksome to some patients. (3) If the lump disappears under x-ray treatment, some patients may refuse operation altogether. (4) It is stated by some that pre-operative irradiation makes subsequent operation more difficult because of increased bleeding. This has not been my experience. The tendency to ooze is a little greater and the tissues are slightly more friable, but on the whole the operation is quite straightforward. (5) If mastectomy is carried out before the skin reaction has developed there is the risk that this may coincide with the healing of the skin flaps, in which case separation of the edges of the wound or sloughing may occur. The optimum irradiation-operation interval is not known. It must be long enough to allow the skin to regain its natural healing qualities but not long enough to allow regrowth of tumour cells. It would appear to be about six weeks.

There is a limit to the scope of x-ray therapy to which I should like to draw attention before considering its indications. Many hold that in certain cases pre-operative x-ray treatment can convert the surgically incurable into a surgically curable case. This is doubtful. The commonest example is the patient with a fixed mass of axillary glands. I believe that if the case is judged clinically incurable by surgery no amount of x-ray treatment will convert it into a surgically curable case however much the tumour mass may seem to disappear.

It is true that the effect of a full course of x-ray therapy can be quite remarkable, and that at the end of treatment in radiosensitive cases no lump may be palpable where previously there had been a fixed mass. It is tempting in these circumstances to proceed to radical mastectomy, but I am convinced that this is wrong. Fixation of the glands implies penetration of their capsule by malignant cells. This in turn implies advanced malignancy, and it is reasonable to suppose that a subsequent attempt at clearance of the axilla will serve only to disseminate the disease. Pre-operative x-ray treatment may render these patients technically operable, but that is not the same thing as rendering them surgically curable. They are surgically incurable.

It is impossible to lay down any hard-and-fast rules for pre-operative therapy. Its application is being extended in two directions.

1 *As an Alternative to Routine Post-operative Therapy*—The uniform application of pre-operative x-ray treatment is not quite so straightforward as it might appear. If the cardinal signs of cancer are absent, a biopsy will be necessary. It would therefore seem prudent for the time being to continue to employ post-operative therapy for the early cases until trials have shown which they may not, that pre-operative x-ray treatment is to be preferred at all stages of the disease.

2 *In the Presence of a Shortage of Skin*—Depending on the size of the tumour (relative to the size of the breast) and the extent of skin involvement, patients fall into one of two groups: those in whom it is judged that primary removal of the breast (and tumour) will leave a defect between the edges of the skin flaps and those in whom it will not leave such a defect. Pre-operative x-ray treatment is of particular advantage for most patients in whom a defect is anticipated.

A shortage of skin, although not invariably present, is commonly found when the breast is unusually small, when the tumour is large, when the tumour is widely attached to the skin, and when the tumour has ulcerated through the skin. A defect between the edges of the flaps has two disadvantages: first, it can heal only by skin graft or by granulations and scar tissue, which form a patch vulnerable to subsequent post-operative therapy, and secondly, and more serious, healing is often protracted so that post-operative therapy is sometimes delayed until it may be useless. If such a defect can be anticipated—and to do this the area of skin available for the flaps must be worked out beforehand and not on the operating table—pre-operative x-ray treatment should be given. Delay in the healing of the wound subsequent to x-ray treatment has not the same significance, as it holds up nothing except the ordinary convalescence of the patient.

### Surgical Treatment

Radical mastectomy for many years has been advocated as the best surgical treatment of Stage I and II cases. Recently this has been challenged, and a plea has been put forward for more conservative surgery.

In 1941 an important experiment was launched in Edinburgh, where it was agreed to try out a uniform method of treatment for all operable cases—simple mastectomy followed by post-operative irradiation to the chest wall and the undissected axilla—and submit the results for statistical analysis. This method is the same as that of Keynes (1937), except that x-rays are substituted for radium and the subpectoral group of glands, if accessible, are removed at the same time as the mastectomy.

In this method Stage I cases are included as well as Stage II cases. The view is taken that if the disease has spread to the axilla surgery will serve only to disseminate it still further, and that if the disease is confined to the breast dissection of the axilla is unnecessary. The five-year survival rate of all operable cases is reported in three groups as follows: 1941–5, simple mastectomy plus post-operative radiotherapy, 56%; 1935–40, radical mastectomy plus post-operative radiotherapy, 44%; and 1930–4, radical surgery only, 35.6% (McWhirter, 1948).

The disadvantages are much the same as those with radium—in particular, the persistence of active malignant cells in the axillary glands after the termination of treatment. That they do persist at least for a time has been proved by carrying out a radical mastectomy after a full course of pre-operative irradiation and examining the axillary and breast material so obtained. Malignant cells were found to persist in the axillary glands of patients treated with x-rays alone in 92% of cases by Adair (1943) and in 65% by Richards (1948).

The question is, Can x-rays in Stages I and II (the only stages in which radical mastectomy is done) restrain the local growth and spread of carcinoma in the axilla more effectively than operative clearance? The answer is not yet known. The advocates of x-rays believe that if the irradiated tissues are not disturbed by operation the cells will eventually either disappear or be rendered harmless by fibrous encapsulation. Those in favour of clearance of the axilla by operation contend that x-rays are only a "holding" technique and that recurrences or dissemination must

be expected between the fifth and tenth years. Time alone will show which school of thought is right. In the mean time, what attitude are we to adopt in the treatment of our operable patients in regard to dissection or non-dissection of the axilla?

### Operable Cases

*Stage I and Stage II (Early)*—Radical mastectomy combined with radiotherapy should remain the treatment of the early case until a better method has been demonstrated—over a seven-year or preferably a ten-year period, since the natural history of untreated cancer of the breast is three years and three months (Greenwood, 1926)—and for these reasons:

1 No other known method has yet produced results as satisfactory over a similar period. In the series of Stage I cases published by Gordon-Taylor (1938) and in the Leeds series of gland-free cases (Ministry of Health Report, 1926), 84% and 91%, respectively, of the patients operated upon were alive ten years later. These figures approximate closely to the chances of survival among the general population in the same age periods and must therefore be regarded as very satisfactory.

2 Radical mastectomy is based on sound pathological and surgical principles. Local mastectomy for cancer violates these principles because it cuts across the path of spread of the disease.

3 The general standard of radiotherapy is not high enough yet to follow out the Edinburgh procedure, even if this was thought desirable.

4 The continued presence of living cancer cells in the undissected axilla despite x-ray therapy has been demonstrated. The danger of these residual cells may be exaggerated and be more potential than actual, but the possibility of their recovering their activity cannot be ruled out. This possibility might be a reasonable risk to take in the more advanced stages of operable carcinoma (late Stage II), but it cannot be so regarded in the earliest stages of the disease, in which the radical operation still offers the best opportunity of clearing all malignant tissues from the axilla.

*Stage II (Late)*—I believe that in late Stage II cases there is a place for the treatment of operable cancer of the breast by simple mastectomy and irradiation of the undissected axilla. Some surgeons feel that all operable cases should have the radical operation, others consider that the radical operation should not be applied as a routine simply because the patient is classified as belonging to Stage II. Not all patients in Stage II are at the same pathological stage in their illness. Age, site, rate of growth, and extent of skin involvement are the factors which help us to separate the later cases from the earlier ones. Experience alone can guide us, but I think a conservative mastectomy without dissection of the axilla should be seriously considered in Stage II patients—assuming first-class radiotherapeutic services to be available—if a combination of two or more adverse factors is present, such as rapid growth, wide involvement of skin by infiltration or ulceration, age over 65, and possibly a peripherally situated tumour, more particularly if it is in the inner hemisphere.

### Inoperable Cases

*Stage III*—This group comprises cases with enlarged supraclavicular nodes on either side, fixed axillary nodes, mobile or fixed axillary nodes on both sides, deep fixation of the breast to the ribs, secondary nodules in the skin, or oedema of the arm. (It will be noted that patients with fixed glands are placed in this category.) Radical surgical treatment is absolutely contraindicated in these patients because they have advanced malignant disease. In special circumstances, such as fungation or a large tumour, simple mastectomy may be indicated. X-ray treatment, judiciously applied, may be of great value in the treatment of glandular masses and skin nodules. Some

surgeons carry out the radical operation on cancers of the breast associated with enlarged supraclavicular glands provided the glands are mobile and not fixed to form a supraclavicular mass. All the evidence points to the danger of any form of surgical treatment in these patients. Operative intervention at this advanced stage can only hasten the patient's end.

**Stage IV**—This group comprises cases with distant metastases in bones, viscera, or lungs. These patients are unsuited for any form of active treatment other than hormonal X rays, however, may help in the relief of pain caused by secondary deposits in bone, particularly when the metastatic process is confined to a solitary deposit—for example, a single vertebra. Although the ultimate prognosis is grave, some of these patients survive for long periods with well-controlled x-ray treatment. The pain of brachial neuritis caused by a supraclavicular mass of glands is similarly relieved.

### The Operative Mortality of Radical Mastectomy

The operation of radical mastectomy is not yet obsolete. Until it is, operative mortality and morbidity must be reduced to a minimum. Cade (1948) has collected the figures of 22 British surgeons. There were 11,014 radical mastectomies, with 182 deaths—a mortality of 1.65%. In my series of 170 consecutive radical mastectomies there was no operative death—that is, no patient died within one month of operation or while still in hospital.

### Summary and Conclusion

It is more than half a century since Halsted first practised his operation for cancer of the breast. While much has been achieved since then by individual effort it is well to remember that a busy surgeon cannot expect to see many more than 500 patients with cancer of the breast. Spread as they must be over 30 to 40 years, conclusions arising from this experience can come only slowly.

It would seem that we have now reached a stage in the history of this disease when it would be of great advantage to be able to test different combinations of surgery and radiotherapy and hormone methods of treatment upon groups of patients on a scale large enough to make the trials of value. Collaboration between individual surgeons as well as between surgeons and radiotherapy centres would make such investigations possible. Collaboration before treatment and the pooling of results afterwards would provide the volume of material which is necessary if expert independent statistical analysis is to be of value, as it can be, in determining future lines of treatment and in determining them within a reasonable span of time.

Early diagnosis is the key to the problem of treatment of breast cancer.

No significant improvement in treatment need be expected until there is wider knowledge of the basic clinical fact that *there is no outward visible change in the appearance of the breast in early malignant disease*.

Amending regulations have been made which relax certain prohibitions in the existing orders affecting the importation and sale of mutton. Caseous lymphadenitis is not regarded as communicable to humans, and the amendments bring the regulations into line with present-day practice in the exporting countries concerned.

## PAPILLOEDEMA IN EMPHYSEMA\*

BY

THOMAS SIMPSON, M.Sc., M.D., M.R.C.P.

Physician Chase Farm Hospital Enfield

Papilloedema rarely occurs in emphysema. Cameron (1933) seems to have been the first to record it. Friedfeld and Fishberg (1934) mention the occurrence of papilloedema in a case of severe right heart failure secondary to pulmonary disease but do not give the cerebrospinal fluid pressure. Meadows (1947) records a case and suggests that the papilloedema was secondary to chronic increased venous pressure and polycythaemia, these in turn being due to the chronic chest condition. Beaumont and Hearn (1948) report a case under the title "Reversible papilloedema due to heart failure" and suggest that the cause is increased pressure in the venous cranial sinuses interfering with the filtration processes of the arachnoid villi.

Although I have studied only three cases, the rarity of the condition prompts me to evaluate the causes of papilloedema in emphysema and to suggest their mechanism.

### Case Reports

**Case 1**—A motor driver aged 54 was admitted to Redhill County Hospital on April 2, 1946. He had had bronchitis for 28 years and orthopnoea for six months. Seven days before admission oedema had developed. On examination he was seen to be extremely cyanosed, orthopnoeic, and oedematous, and ascites was present. The veins of his face were dilated, his eyes were prominent, the conjunctivae were congested, and he complained of poor vision. Bilateral papilloedema and engorged retinal veins only were seen on fundal examination. The venous pressure was raised to 4 cm above the sternal angle. Clinical and x-ray examination revealed emphysema, numerous basal rales, and cor pulmonale. The blood pressure was 140/100. The red cells numbered 5,620,000 per c.mm., and the haemoglobin was 120%. Lumbar puncture could not be done owing to his general condition. On April 27 the papilloedema had receded, the retinal veins were less engorged, and he could see better. Clinically the venous pressure was now at the sternal angle level, the oedema had gone, his vital capacity was 2 litres, and the blood pressure was 135/90. Also the eyes were less prominent and his head was less congested. He was readmitted on Aug. 7, 1946, in semi-coma with massive oedema and twitching of the arms. The neck veins were not visibly distended and the blood pressure was 180/90. He was discharged on Sept. 25 with no oedema and minimal cyanosis. He was readmitted on Nov. 25, 1946, with gross oedema, gallop rhythm, and a venous pressure of 7 cm above the sternal angle. He died four days later. The fundi were not commented on in the last two admissions. At necropsy the lungs showed gross emphysema, and although the medium branches of the pulmonary artery showed a well-marked degree of atheroma the smaller branches were normal microscopically. The heart weighed 500 g., the right ventricular wall being 1.5 cm. thick and the left normal. The brain was not examined.

**Case 2**—A builder's labourer aged 46 years was admitted to St. Mary's Hospital, Paddington, on Jan. 5, 1948, with congestive failure. Since 1925 he had had winter bronchitis, and in December, 1947, he was orthopnoeic. Nocturnal ankle oedema started in May, 1945, but it troubled him only towards the end of 1947. On examination he was deeply cyanosed, his eyes were prominent, and oedema and ascites were present. Emphysema, numerous basal rales, and cor pulmonale were present. The blood pressure was 140/80. On Jan. 14 the fundi showed bilateral papilloedema, with extreme engorgement and tortuosity of the retinal veins, normal retinal arteries and one hard white exudate in the right fundus. At this time the venous pressure measured 2 cm in the neck, the oedema had gone (temporarily), but the deep cyanosis remained and he was extremely breathless on movement in and out of bed. The red cells

\*Paper read before the Middlesex County Medical Society on March 18, 1948.

numbered 5 700,000 per c mm and the haemoglobin was 120%. Renal investigations were normal, and the vital capacity never exceeded 1.5 litres. On Jan 16 the CSF pressure was 215 mm of water and the venous pressure 9.8 cm above the sternal angle. He was discharged on Feb 13 with the fundal appearances unchanged.

**Case 3**—A summary of the clinical notes of this patient is contained in the appendix to the paper by Howarth *et al* (1947). I quote it in full and add further post mortem details (Lennox, 1948, personal communication) relevant to my discussion.

Male aged 42. Chronic bronchitis and asthma 10 years. Cyanosed, irritable and forgetful 1 year. Deep cyanosis, oedema and ascites. Vital capacity 1,100 ml. ECG SR. Right axis shift. ST, depressed. P 0.25 mv. X-ray pulmonary arteries enlarged. Heart moderate enlargement. Blood RBC, 5 300,000 per c mm, haemoglobin 93%. Numerous fundal haemorrhages. Papilloedema developing later. CSF pressure greater than 300 mm. No improvement from oxygen and thiouracil. Death after two months. Post mortem heart weight 440 g. Left ventricle normal. Lungs emphysema, slight atheroma of pulmonary artery intimal thickening of small branches of pulmonary artery.

The surface veins of the brain were engorged to an exceptional degree and the convolutions were slightly flattened. Serial section of the brain showed prominent veins. The authors had found the venous pressure to be 5 cm above the sternal angle, the blood pressure was 118/69, and the arterial O<sub>2</sub> saturation was 42%.

### Discussion

Bilateral papilloedema is generally associated with and attributed to raised CSF pressure in the cranial cavity. Patients with papilloedema usually have a higher CSF pressure than those without, in cerebral tumour (Ayer, 1929), for example, or hypertension (Pickering, 1933-4). Of the three cases reported here two showed a raised CSF

logist, Mr C B Goulden. Owing to the oedema the CSF pressure could not be determined. In two other cases of congestive failure the CSF pressure measured 30 and 22.5 cm and the corresponding venous pressures were 21.5 and 15 cm. In neither case was papilloedema seen.

Pickering (1942) quotes a case of bronchial carcinoma obstructing the superior vena cava in which the venous pressure was raised by 30 cm and the CSF pressure was 42 cm, yet papilloedema was absent. It is uncertain why these venous and CSF pressures should be unassociated with papilloedema. These cases with high CSF pressure and no papilloedema differ from the cases of emphysema I have described with high CSF pressure and papilloedema in that in the former venous pressure is generally raised in the head and neck, while in the latter the general venous pressure is more or less normal. For instance, the highest venous pressure recorded was 9.8 cm above the sternal angle (Case 2) and in this case papilloedema was seen when the venous pressure measured only 2 cm in the neck.

In the three cases of emphysema, therefore, the raised CSF pressure cannot be ascribed to raised venous pressure, for this on measurement was normal or nearly so. A different cause must be found, and this cause may be sought in the essential functional disturbance of emphysema—namely, deficient haemo-respiratory exchange. In emphysema the O<sub>2</sub> saturation of the arterial blood is low and its CO<sub>2</sub> content high (Meakins and Davies, 1925). Both these changes affect the intracranial vessels, that of CO<sub>2</sub> excess being much more conspicuous. In five patients with emphysema and cor pulmonale without papilloedema who died at this hospital the dilatation of the cerebral veins seen at necropsy was a striking feature (see also Case 3).

Wolff and Lennox (1930) observed the pial vessels of cats directly through a trephine hole in the skull. In two experiments the animals inhaled a mixture of room air and approximately 5% CO<sub>2</sub>. Although the CO<sub>2</sub> content of the blood was increased by only 2% there was a 17% increase in the size of the observed pial artery. At the same time the CSF pressure, measured in millimetres of Ringer's solution, rose from 40 to 60. However, Dumke and Schmidt (1942-3), in experiments on the cerebral blood flow in 3 to 6 kg monkeys, cast doubt on the validity of these observations, finding that anoxaemia was a more powerful dilator of the cerebral vessels than CO<sub>2</sub>. They, however, draw attention to the fact that none of their animals showed appreciable hyperpnoea during anoxaemia. Had they done so the reduction in the arterial CO<sub>2</sub> tension might have caused constriction of the cerebral vessels, and this sufficient to counteract the dilator effect of anoxaemia. The increase in cerebral blood flow resulting from anoxaemia may therefore have been considerably greater than it would have been under more nearly normal circumstances.

To explain the difference between this work and that of previous workers Schmidt (1944) says that either the response of the cortex is not representative of the great

TABLE I

Case	Sex	Vital Capacity in Litres	CSF Pressure in mm of Water	Venous Pressure in cm above the Sternal Angle (S.A.)
A	M	1.1	50	1
B	M (died)	Too dyspnoeic	160	S.A. +
C	M (died)		100	5
D	F	0.7	70	0
E	M	1.3	45	11
F	F	1.5	80	0
G	M	1.5	135	0

pressure, as did Meadows's (1947) case. In seven cases of emphysema and cor pulmonale without papilloedema I found the CSF pressures to lie between 45 and 160 mm of water (Table I). It seems probable, therefore, that the papilloedema in emphysema is likewise due to a raised CSF pressure.

In congestive cardiac failure and obstruction of the superior vena cava very high venous pressure may be present without papilloedema. In one case of congestive failure the venous pressure measured 35 cm above the sternal angle, yet only haziness of the disk margins and congestion of the retinal veins were seen by our ophthalmologist.

TABLE II

Case	Age	Diagnosis	CSF Pressure in mm. of Water					Hyperpnoea During the Inhalation
			During Inhalation of CO <sub>2</sub>		After Cessation of Inhalation of CO <sub>2</sub>		After Voluntary Hyperpnoea — 6 Breaths	
			Initial	Final	Max Rise	Final		
A B	43	Fibrositis	75	145 (60)	155 (70)	75 (142)	—	Nil

E F	50	Orthostatic albuminuria	80	165 (45)	240 (65)	90 (165)	—	+
G H	24	Neurosis	78	165 (90)	180 (120)	78 (205)	63	Nil
I J	48	Headaches	75	190 (105)	—	—	50	Nil
K L	34	Pleural effusion	120	200 (40)	245	120 (95)	75	+

The numbers in parentheses show the time in seconds after the beginning of the experiment that the pressures were recorded.

mass of brain substance or else species differences exist (Note that in Case 3 serial section of the brain showed prominent veins) He concludes that at the present time it seems probable that both may be true. If these observations of Dumke and Schmidt (1942-3) are correct, then priority must be given to  $O_2$  lack over  $CO_2$  excess as a cerebral vascular dilator, but this in no way invalidates my conclusions, since both are present in the cases under discussion.

Dixon and Halliburton (1913-14) studied the effects of various substances on the secretion of CSF from a wide cannula placed in the subcerebellar cisterna of dogs. They found that the inhalation of  $CO_2$  increased the secretion markedly. Further, they (1914) studied the effect on the CSF pressure of inhalation of concentrations of  $CO_2$  varying from 3 to 10%. In a few seconds after inhalation of the  $CO_2$  mixture the CSF pressure rose steeply and after stopping the inhalation it fell, but more slowly than it rose. They concluded that of all the conditions which influenced CSF secretion the most important were a deficiency of  $O_2$  and an excess of  $CO_2$  in the blood.

In view of these findings it was decided to observe the effect of inhaling  $CO_2$  on the CSF pressure in human subjects. In six patients not suffering from intracranial or vascular disease the effect on the CSF pressure of inhaling a mixture of 7%  $CO_2$  in 93%  $O_2$  through an oronasal type B.L.B. mask, to which they had been previously accustomed, was observed.

The CSF pressure was recorded after it had become stabilized during natural respiration,  $CO_2$  mixture was then inhaled for a varying period of time and then discontinued. It was found that after cessation of inhalation the CSF pressure continued to rise to a maximum. The CSF pressure and times were recorded at the end of the period of inhalation, at the point of maximum rise, and finally when the CSF pressure had returned to its original level. In three patients the effect of voluntary overbreathing (six breaths) was determined. The results are shown in Table II.

These observations show clearly that a rise of blood  $CO_2$  raises the CSF pressure in the human subject. They thus support the hypothesis that raised CSF pressure in emphysema is due to  $CO_2$  retention in the blood.

A further possibility must be mentioned. Polycythaemia was suggested by Meadows (1947) as a partial explanation of the papilloedema in his case. Sir Charles Symonds supported this suggestion and said that he had seen similar fundal changes in a case of primary polycythaemia. Loman and Dameshek (1944) describe papilloedema in a man aged 41 with a five-year history of polycythaemia. The general venous pressure was but 8 cm and the CSF pressure 380 mm. The red cells numbered 81 to 9 million per cmm and the haemoglobin was 136 to 142%. After venesection the papilloedema subsided, leaving a slight degree of optic atrophy in one disk. They were convinced by intra-jugular-pressure studies that venous sinus thrombosis had not occurred. However, none of the cases I have described had a degree of polycythaemia comparable to these cases.

### Summary

From a review of the literature and the study of three patients the hypothesis is put forward that papilloedema in emphysema results from a raising of the intracranial pressure.

A rise in general venous pressure does not provide a sufficient explanation and an intracranial factor is postulated.

It is suggested both from a review of animal experiments and from observation on man that  $O_2$  lack and  $CO_2$  accumulation in the arterial blood in emphysema may produce cerebral vasodilatation adequate to raise the CSF pressure to above the level producing papilloedema.

While polycythaemia may be a contributory factor in certain cases I do not think that it played a part in the cases under discussion.

I studied the cases through the kindness of Dr G. H. Jennings, Redhill County Hospital, Edgware, Professor Pickering, St. Mary's Hospital, and Dr R. Harrison, British Postgraduate Medical School. For the necropsy findings in Case 1, I am indebted to Dr H. Paterson, Redhill County Hospital, Edgware, and for those in Case 3 to Dr Bernard Lennox, British Postgraduate Medical School. I wish to thank Professors Pickering and McMichael for their help and guidance in the preparation of this paper.

## OUT-PATIENT ELECTRIC CONVULSION TREATMENT

BY

Sir W. P. MALLINSON, Bt, MA, BM, MRCP  
 Honorary Assistant Psychiatrist, St. George's Hospital

Electric convulsion treatment has many applications in psychiatry, and the indications for its use in severe mental illness, particularly in the depressive psychoses, are generally clear and well known. It is proposed in this paper to report upon its use as out-patient treatment for less severe and for earlier cases and to attempt to define the indications for and the limitations of such treatment.

In 1733, when the founders of St. George's Hospital met, they were influenced in their choice of the site at Hyde Park Corner by the fame of the locality as a place "where is good air for cure of consumptions, melancholy, and other infirmities." In the light of this pioneering approach to the treatment of melancholy by physical methods it was perhaps not inappropriate that the hospital should provide one of the first services, if not the first, of out-patient E.C.T. clinics. These clinics have been held regularly since November, 1941, and Table I shows the growth of the service. The clinics were initiated by Dr. William Sargent, and

TABLE I—Total Number of Patients Treated

1942	1943	1944	1945	1946	1947
37	48	32	30	112	180

during the war years Dr. Sargent and Dr. E. T. O. Slater, were in charge. Up to the spring of 1946 there was one session each week, now there are three—on Monday, Wednesday, and Friday. The increased frequency of the sessions not only allows more patients to be treated but enables more intensive treatment to be given where necessary, so that more rapid improvement can be obtained and more seriously ill patients treated.

**Technique**—The technique used in the early days is still followed, and the training and keeping together of an experienced staff of assistants is regarded as of great importance. The sister-in-charge is the leader of the team and is responsible for instructing new recruits in their duties. During the treatments Sister attends to the electrodes, the mouth gag, the administration of oxygen, and supports the patient's chin. Oxygen is given from the moment that the shock is applied until the patient is again breathing well and has a good colour, by this means the more severe degrees of cyanosis are generally avoided. The patient lies upon a firm trolley with no mattress, but with one low pillow for the head and a small sandbag under the dorsal spine. Moderate restraint is used by one assistant on each shoulder and arm, while another assistant, and in the case of specially muscular patients two more, controls the pelvis and lower limbs. Thus, in addition to the psychiatrist and sister, at least three nurses are required—a considerable expenditure of man- and woman-power. However, the method has worked smoothly and with an almost complete freedom from undesirable complications for a long time. During the period of 12 months reviewed later in this paper, in which 170 cases were treated, treatment was terminated in one case after a fracture of the 6th dorsal vertebra had been revealed radiologically. This has caused no permanent disability. No other fractures or dislocations occurred during this period, nor were there any other physical mishaps. The presence of an adequate staff enables the actual treatment to be given and the patient to be transferred to the recovery room with the minimum wastage of time. This is a factor of great importance, since time saved in giving treatment means time gained for interviewing patients and their relatives in order to assess the progress of the illness and the effect of treatment. It is quite unjustifiable ever to give treatment unless such an assessment has been made.

### Follow-up Questionary

During May, 1947, a follow-up letter was sent to 150 of the patients who had been treated in the earlier years. Many of these patients had had their treatment two, three, four, or even more years before receiving the questionnaire, and the minimum period was nine months.

Eighty-five replies were received, a large number of the remaining 65 letters having been returned marked "Gone away"—partly, no doubt, on account of bomb damage to houses and other factors connected with the war. Table II presents a comparison of those patients who reported themselves as being well and those who still had symptoms.

From this follow-up inquiry certain facts emerged. 64% of the patients treated were discharged as recovered or much improved. Some half-dozen had relapsed and approximately the same number had subsequently recovered, although their response to ECT had not been very good and they had been discharged as ISQ or only slightly improved. The duration of illness before treatment was considerably greater in the group who responded badly. The chance of recovery was better if there were no neurotic, psychotic, or psychopathic symptoms other than those of the depressive illness, but such symptoms were by no means a bar to recovery, since 50% of those patients in whom they occurred in association with depression recovered. The existence of hysterical, anxiety, or obsessional symptoms, mild mental defect, psychopathic traits, and sexual abnormalities did not prevent a patient being relieved of depression. In such cases the specific effect of ECT appeared to lie in its influence upon mood, and once this had been corrected the neurotic symptoms in many cases, though not in all, also cleared up. Those patients who had not previously had a mental illness showed rather better results

than those who had. The average number of treatments for both the recovered and the not-recovered group was five. The best results were obtained in the 31-40 age group and the worst in the older age groups—i.e., 51 and

Psychiatric Unit,  
St George's Hospital,  
15, Knightsbridge, S W 1  
194

Dear

It is now months since you received your last electrical treatment in the Out patient Department at St George's Hospital, and I should be very interested to hear from you how you are getting on. It would be most helpful if you would answer the following questions.

- 1 Have you regained your normal health?
- 2 Do you still suffer from symptoms which trouble you? If so, what symptoms?
- 3 Have you been under any other hospital—  
(a) as an Out-patient?  
(b) as an In-patient?  
If so,  
(a) When?  
(b) Where?  
(c) For how long?
- 4 Are you now doing the same work as you were before your illness? If you have changed your work, would you please say why? Do you have to take time off work for illness?
- 5 Are you able to do your work in a satisfactory manner?
- 6 Are you able to take part in social activities?
- 7 Are there any other points you wish to mention?
- 8 Do you consider that you derived { much  
from the electrical treatment? { little benefit  
no

I should be most grateful if you would answer these questions, as it will show me how well you are and also help in the treatment of other patients.

Yours sincerely,

above. There was no significant difference in the results as between men and women or married and single persons.

Of these 85 patients 78 (92%) had depressive illnesses, three were schizophrenic, and there was one depersonalization syndrome, one obsessional state, one paranoid state,

TABLE II (Follow up Series)

	Recovered	Not Recovered
Condition at end of treatment		
Recovered or much improved	48%	16%
Slightly improved	2%	3%
Not improved	11%	19%
Total	61%	39%
Married	63%	37%
Single	58%	42%
Average duration of illness before treatment	9 months	14 months
Neurotic features	50%	50%
No neurotic features	71%	29%
Previous mental illness	55%	45%
No previous mental illness	66%	34%
Average number of treatments	5	5
Sex

Women	60%	40%

and one psychopathic personality. Sixty-nine of these patients were able to continue to live at home during and after the treatment, ten were admitted to Sutton Neurosis Centre, four to observation wards or mental hospitals, and two were referred back to the psychiatric out-patient departments of other hospitals. During the period in which these patients were treated there was no in-patient accommodation for psychiatric cases at St George's. Sixty-six patients continued at the same or equivalent work after treatment, four replied that they had been able to take a better job, seven said that their working capacity had deteriorated, and 21 reported that they still had to take time off on account of psychiatric symptoms.

In reply to the final item in the questionnaire 48 patients reported that they had derived "much" benefit from the electrical treatment, 18 reported some or little, and 19 none. The last group included one patient who answered, "None, except that it cured my depression"—a rather curious but perhaps not insignificant tribute to the specific effect of ECT upon mood. Five patients stopped treatment on account of fear or dislike of it, one because his cardiac condition gave some cause for concern after his first treatment although no permanent damage ensued, one moved away from London and continued treatment at another clinic, while one was obliged to stop because no one could be found to accompany him to the clinic. Many patients amplified their answers to the final question.

The following extracts are selected from the most appreciative answers, although there were many others equally favourable.

(1) Mrs A, aged 39, a clerk, a depressive state with hysterical features, 8 months' duration, received 2 ECT in March, 1944. "As you know, I did not have the full treatment—I had only two, after being ill eight months I was completely cured."

(2) Mrs B, aged 49, housewife, involutional depressive state, five months' duration, received 4 ECT in April-May, 1945. "I consider that the treatment saved my life."

(3) Mr C, aged 37, a business manager, depressive state, mainly endogenous, 3 months' duration, received 3 ECT in July, 1946. "A complete cure, with nerves and general health and confidence restored to normal."

(4) Mr D, aged 39, an electrical engineer, reactive depressive state, two years' duration, received 4 ECT in March, 1943. A very great benefit. It was the most effective treatment I have ever encountered in my life. I was ill for two years before treatment and was made bright and well after four shocks."

(5) Miss E, aged 47, a shorthand-typist, moderately severe depressive state with mixed reactive and endogenous features, two months' duration, received 3 ECT in January-February 1946. "I think it was simply marvellous. It changed me from a species of stone to a living person, and I cannot speak too highly of it."

(6) Mrs F, aged 48, housewife, endogenous depressive state nine months' duration, received 5 ECT in May-June, 1946. "I consider the treatment wonderful, after five treatments I was my old self and mentally keep well."

The following extract is from a letter from a patient treated in private practice for a moderately severe puerperal depressive state.

I could never have believed I could feel so fit and happy in so short a time after seven weary months. I have taken a completely new lease of life and can really enjoy and appreciate my baby for the first time since her birth in April."

These extracts are published in the hope that they may help to correct the impression produced by a number of ill-informed and prejudiced statements which have appeared in the medical press. Such statements, however sincere, can only be regarded as pernicious, since they are calculated to dissuade doctors from referring their patients for ECT. No greater disservice can be done to the depressive patient than to withhold him from consideration, at least for ECT.

### September, 1946–August, 1947

During this period of 12 months 170 patients received ECT in the out-patient department, of these, 103 were women and 67 men. In Table IIIa the diagnoses in this series are related to the results of treatment.

Table IIIb provides a comparison of the results in depressive states with those in all other conditions treated.

Others	1	2	3	8	14

Six patients have already relapsed, five refused to continue the treatment, and ten ceased to attend. In one case, previously mentioned, treatment was terminated after a fracture of the 6th dorsal vertebra had been revealed radiologically.

Of the men 57% were classified as recovered or much improved, as compared with 53% of the women. The results in the lowest age group of women compared unfavourably with those for the same group of men, while in the two highest age groups the men responded less well than the women. The numbers treated were too small for any conclusions to be drawn from these observations, but Table IVb and IVc, by condensation of the categories, present certain of the findings in this series in a more striking manner.

TABLE V—Average Number of Treatments

	Men	Women
Recovered	5	6
Much improved	6	8
Slightly improved	4	6
IS Q	3	7

In all the categories the number of treatments received by the women exceeded that given to the men. Treatment is usually given twice a week, in the milder cases once a week may be often enough, but in the more severe cases the quicker improvement obtainable by giving three treatments for the first week or two can reduce the risk of suicide and prevent certain patients having to enter hospital for inpatient treatment. In a suitable and uncomplicated case recovery can be expected after from two to ten treatments.

#### Disposal

Of these cases 131 were able to remain at home during and after treatment. The disposal of the remainder was as follows: 17 admitted to the psychiatric ward in the Atkinson Morley Branch of St. George's Hospital at Wimbledon (all women, since the male side had not yet been opened), 6 admitted to Sutton Neurosis Centre, 2 admitted to the York Clinic, 1 admitted to Roffey Park Neurosis Centre. One patient was admitted to the Obstetric Unit at St. George's for termination of pregnancy after two treatments, this woman had a severe suicidal depression in a setting of low intelligence. Three patients are continuing to have maintenance treatment—in one case once a fortnight (22 treatments in the year), and in another four to five treatments every 10 to 12 weeks. These are cases which respond excellently to ECT but soon relapse, and the maintenance treatment is being given as a conservative alternative to leucotomy so far with good results. Out-patient treatment offers special advantages for such cases as these, and it is anticipated that the number receiving a periodical maintenance dose will increase.

#### Sources

Of the series of cases 137 came to the clinic through the psychiatric out-patient department, having been referred either by their own doctors or from other departments in the hospital, or from the psychiatric out-patient departments of other hospitals where there was no out-patient ECT service. Thirty-three were referred to the clinic by members of the honorary staff of the unit.

### Selection of Cases for Out-patient Treatment

#### 1 Psychiatric Indications

By means of a rigorous selection of cases it is possible to achieve an extremely high proportion of successful results with ECT. The rate of remissions in the manic-depressive or endogenous type of depressive state varies in most reports between 80 and 100%. The depressions of middle and later life respond very well and reactive depressions often give excellent results. Of the 92 patients in the recent series reported in this paper who responded well enough to be classified recovered or much improved 87 (95%) had depression as the predominating symptom and had been given a diagnosis of depressive state, whether endogenous, involuntal, or reactive. The comparatively poor results in other types of illness revealed in Table III may well suggest that the range of case material which has been subjected to ECT has become rather too wide. On the other hand, where the patient stands to gain so much should the treatment be successful, it would be unjustifiable to restrict its use to those cases which present only the clearest indications. The special value of out-patient ECT is in the case which without it would become so severe that admission to a mental hospital, possibly under certificate, would become inevitable, and in the less severe case where the patient despite prolonged ill-health, would not agree to become a voluntary patient. Out-patient treatment offers such patients a chance to regain their mental health with a minimal disruption of their way of life. The limited

facilities available at the present time for inpatient psychiatric treatment constitute another powerful reason for treating as many as possible as out-patients. It is worth while, therefore, to accept for treatment a certain proportion of atypical or borderline cases in which the clinical indications for ECT are disputable.

The case of hysteria (Table IIIa) which recovered after two treatments may perhaps be cited as an example. This was a case of recurrent hysterical aphonia which was resistant to psychotherapy and a quick cure of which was called for because the patient was going abroad. The case of paranoid state classified as much improved was one among the large group of delusional insect infestations which are well known in the skin departments. This woman believed that small insects circulated in her blood stream as the result of a therapeutic injection which she had received many years ago. The insects left the blood stream at night to torment her with their stings and bites. She had severe excoriations of the pubic region and vulva from scratching. She was depressed, was much under weight, and had not slept properly for many months. Her response to ECT was dramatic: she stopped scratching and the skin lesions healed quickly, she slept well, gained weight, and became cheerful and sociable. Admittedly she gained no insight, but she was happy in the belief that the electrical treatment, which she described as "wonderful," had disinfested her blood stream.

At the same time the indiscriminate use of ECT cannot be too strongly condemned. It is far simpler to press the switch on the set than to undertake the psychotherapeutic and social measures called for by many cases of neurosis, and the temptation to adopt the quicker and simpler course is obvious. Such misuse can only bring the method into disrepute, since, apart from the large number of cases which will not improve, there will undoubtedly be some which are made worse—for example, the intellectual obsessional and the very tense anxious patient in whom there is no evidence of depression. Even in the most suitable case the neglect of social, sedative or psychotherapeutic measures may impair the result, while in borderline cases such measures may be decisive as between success and failure.

It is clear that *depression* is the indication *par excellence* for out-patient ECT, and, while it is well known that depression can be disguised in many ways it would appear to be established that unless depression exists recovery cannot be counted on with much confidence. The diagnosis of mild and atypical forms of depressive illness is then the key to success, and it is admittedly often extremely difficult. Recurrent mental illness, even where the presenting symptoms are, for example, obsessive-compulsive or those of the depersonalization syndrome rather than frank depression, is suggestive, as are recurrent attacks of hypochondriasis (the so-called "manic-depressive equivalents"). For the sake of clarity an attempt has been made to distinguish among individual symptoms, between cardinal and subsidiary symptoms. It is not suggested that the list is by any means complete, but it is felt that where two or more of the former exist in combination with some of the latter the giving of ECT should be seriously considered. Where only one cardinal symptom is present the indication for ECT is less definite, but it may be strengthened by the pressure of subsidiary symptoms.

(a) *Cardinal Symptoms*—Mood persistently depressed. Morning-evening variation of mood (with some lessening of the degree of depression towards evening). Affective loss (often expressed as loss of interest in any kind of activity or of feeling towards relatives and friends). Retardation (often showing itself as difficulty in getting through the ordinary day's work—"everything seems too much trouble" or "such an effort").

Indecision, perplexity, agitation Ideas of self-reproach, delusions of poverty Ideas of reference Avoidance of social contacts in a normally sociable person I do not seem to be able to enter into conversation now"

(b) *Subsidiary Symptoms*—Insomnia, especially difficulty in getting off to sleep, associated with a pressure of worrying thoughts Irritability Excessive fatigability Inability to concentrate Anorexia Loss of weight Constipation Amenorrhoea Diminution of sex drive Hypochondriasis

It would be remiss to conclude this section without emphasizing the importance of *early* treatment, not only in allowing many cases to be treated as out-patients who would otherwise require admission to hospital, but also in preventing the development of secondary reactions—e.g., hysterical elaboration and habituation, which are common complications of prolonged mental as of prolonged physical illness

## 2 Physical Factors

The physical contraindications to ECT have been gradually narrowed down as experience of the treatment has increased. Patients over 70 years old and pregnant women have been successfully treated. It has been pointed out that chronic epileptics seldom come to serious harm as the result of a fit, and it is perhaps even less likely that harm will come from a fit in the controlled conditions of the clinic. Certain cardiovascular disorders, such as aneurysm, coronary disease, and auricular fibrillation, still give cause for concern, but each case must be considered on its merits and the seriousness of the mental condition weighed against the physical risk. Hypertension, pulmonary tuberculosis, severe osteoarthritis, recent fractures, peptic ulcer, and some other conditions which were formerly regarded as contraindications are no longer so regarded since the introduction of curarization to diminish the violent muscular contractions of the convulsion. The occasions on which curarization is to be considered essential are infrequent, but it can enable certain patients to have ECT who would otherwise be debarred. For such patients the technique using thiopentone and curare, so well described by Hobson and Prescott,<sup>1</sup> is followed

## 3 Social Factors

A relative or friend must be available to escort the patient home after each treatment. Although the post-epileptic confusion almost always clears quickly (except in a few elderly patients with degenerative cerebral changes) and the patient is able to leave the clinic within an hour and a half of receiving treatment, he may still be a little muddled and absent-minded, and the availability of an escort is a *sine qua non*.

Patients who live entirely alone are unsuitable. Apart from the occasional persistence of some degree of confusion and absent-mindedness, there is a risk, albeit a slight one given a careful selection of cases, of a sudden swing from depression to hypomania.

Patients who live very far away are, in general, unsuitable for out-patient treatment. A train or motor journey of much more than one hour's duration after treatment is undesirable. Whenever possible, such patients are asked to make arrangements to stay with relatives or friends in London.

Patients doing intellectual work sometimes find considerable difficulty in carrying on with it during treatment owing to the temporary memory defects which occur. Such difficulties may cause a secondary increase in their depression and seriously retard recovery, and intellectual workers are usually advised to stay off work. Many patients, on the other hand, manage to keep at work apart from the treat-

ment days. In the case of housewives, it is often necessary to make arrangements for lessening the burden of household duties and the care of children, usually this can be done by enlisting the help of relatives. It cannot be too strongly emphasized that neglect of such measures or of a full inquiry into the social and domestic background may seriously impair the result of treatment.

## Conclusion

In the early days of convulsion treatment the method was regarded with distrust as well as distaste by many if not most psychiatrists. It is admittedly unpleasant to watch, and the scientific basis of its results is unknown. The objection that it is possible to apply it in ignorance of the dynamic psychopathology of the illness is, however, hardly valid, since it is through a study of the psychopathology alone that the true indications for ECT can be elicited and progress assessed. That shocks can be given unskilfully and without proper psychopathological investigation is clearly not a criticism of the method itself but a warning against careless administration. But perhaps the most widely held objection was that convulsion treatment appeared to be a very drastic and hazardous interference with the natural history of an illness which would, at least as often as not, ultimately clear up without it. At the present time it can be said that very few psychiatrists who were called upon to treat depressed patients before the introduction of convulsion treatment and who have now had any considerable experience of ECT would consent to work in a clinic where it was not available. This change of attitude is attributable to two facts which have been learned by experience. (1) it has been proved that, given a sound technique, the physical risks are extremely slight, and (2) ECT can and does cut short by many months or even years illnesses which might eventually clear up spontaneously, but which might equally well become chronic or end in suicide. The social and economic significance of this and the benefit to the patient through the curtailing of his suffering need no emphasis.

Certain objections are still raised on the score that the treatment is greatly disliked or dreaded by the patients. This has been much over-emphasized. Some patients do complain of transient unpleasant after-effects, such as nausea, headache, muscular pains, and absent-mindedness. But rarely are such symptoms so severe or so persistent as to necessitate termination of treatment, nor is fear of the treatment at all a common cause of premature termination. Where fear or dislike is so severe as to make a patient unwilling to continue it, it is more often than not evidence of incorrect selection of a patient who would be unlikely to benefit from the treatment. The typical depressive patient willingly puts up with such minor and transient discomforts, if they occur, in exchange for relief from his depression. He comes regularly and punctually to the clinic without needing persuasion. One woman patient, a case of recurrent depression, in whom the predominating symptom was a very severe and distressing form of depersonalization, experienced an exacerbation of her depersonalization to a terrifying degree during the recovery period after each treatment. "It seemed as if the horrible dread I have had of losing my identity was enormously increased." This patient suffered intense anxiety during the recovery period, but she came regularly for treatment and made a complete recovery after six shocks. Some patients, having once had an attack of depression relieved by ECT, report spontaneously for further treatment when they feel that they may be about to relapse or to have another attack.

Electric convulsion treatment, does, in fact, give results which outweigh all objections so far raised against it, and in the present state of knowledge there is no adequate substitute for it.

## A CASE OF GROSS OVERDOSAGE OF SOLUBLE PHENYTOIN

BY

T N NAUTH-MISIR, MB, DCH

*Assistant Medical Officer Oldchurch County Hospital Romford*

Soluble phenytoin is an anticonvulsant now widely used in the treatment of idiopathic epilepsy. The exact site of its action has not been elucidated, although it is generally appreciated that it acts differently from phenobarbitone. Toxic effects due to overdosage have been classified by Blair (1939) into (a) nervous symptoms consisting of giddiness, blurring of vision, diplopia, clonic spasm, tremors, muscular irritability, ataxia, and nystagmus, (b) mental symptoms consisting of euphoria, excitement, irritability, confusion, delusions, hallucinations, dullness, and depression, (c) cutaneous eruptions varying from a slight erythema to a scarlatiniform or morbilliform rash, and (d) gastro-intestinal symptoms such as nausea and anorexia. Other toxic effects include fever and swelling and tenderness of the gums. These toxic effects have been noted in the course of therapeutic usage of the drug and are quickly relieved by reduction of the dose or temporary withdrawal of the drug.

The following case of gross overdosage (self-administered) is, I think, worth recording.

### Case Report

A single young woman aged 18 was admitted to Oldchurch County Hospital on the evening of Feb 12, 1948, with a history of having swallowed a total of 250 tablets of soluble phenytoin (1½ gr (0.1 g) each) about eight hours previously. According to her previous history (obtained from her mother) she had been suffering from idiopathic epilepsy since the age of 14 and had been attending a hospital for treatment, which consisted of 1 gr (0.65 mg) of phenobarbitone and 1½ gr of soluble phenytoin thrice daily. This seemed to keep her attacks fairly well under control. During the past year, for instance, she had had only three attacks. Between attacks she appeared quite normal, apart from occasional outbursts of "temper," and was able to manage her work at a sack-making factory satisfactorily. On the day before her admission to hospital her mother had collected a three months supply of phenobarbitone and soluble phenytoin (the latter consisting of 250 tablets). The mother, it must be added, controlled the supply of tablets to her daughter.

Shortly before her admission to hospital, and about six hours after taking the tablets, she had vomited once, the vomitus consisting of some whitish material only.

On admission the patient was seen to be a well developed and well-nourished young woman. She was conscious and co-operative. Her main symptoms were double vision, intense generalized headache, and severe giddiness. There was gross cerebellar ataxia so that she was quite unable to sit up in bed or to stand up. When she tried to do so she swayed and reeled in all directions. There was coarse vertical and horizontal nystagmus. No ocular palsies were demonstrable and the pupils reacted normally to light and accommodation. Visual acuity seemed unimpaired and there was no deafness or tinnitus. The speech was slurred. The other cranial nerves appeared normal. Intention tremor was pronounced and gross ataxia of the lower limbs was present. There was no paresis, paralysis, spasticity or hypotonia of the limbs. Sensation was unimpaired. None of the deep tendon reflexes were elicited. The plantar responses were extensor. The fundi appeared normal. Apart from a pulse rate of 110 and a blood pressure of 170/100 the other systems remained unaffected. No abnormality was detected in the urine. Gastric lavage produced a thin white solution.

As the patient was conscious and felt comfortable while she was kept flat in bed, no special treatment seemed to be indicated. On Feb 13 the clinical picture remained much the same. She had slept well during the night and the headache had almost cleared up. Diplopia was absent. The pulse rate had dropped to 90. There was, however, much nausea and vomiting of bile stained fluid material. Next day the headache had cleared up and the vertigo was much improved. She could now sit up in bed without reeling. Horizontal nystagmus was still present and the speech was still slurred. The plantar responses were now flexor. The blood pressure was 90/60.

On Feb 16 the ataxia had completely cleared up and she was able to stand and walk about normally. The speech was also improved. There was still some degree of horizontal nystagmus, however. Next day the nystagmus was absent and she was regarded as having completely recovered. On Feb 22 she had a major epileptic attack. On Feb 28 she was discharged from hospital.

Unfortunately it was not possible to estimate the soluble phenytoin levels in the blood, urine, cerebrospinal fluid or gastric contents. Examination on Feb 13 showed—urine acid trace of albumin present, no other abnormality detected. blood urea 26 mg per 100 ml, alkali reserve carbon dioxide content, 46 vols per 100 ml, blood haemoglobin 80% (Haldane) red cells, 4,100,000, white cells, 7,800, platelets 180,000, bleeding time 4 minutes.

### Comment

Both the patient's and her mother's evidence confirmed that the whole of the three months' supply of soluble phenytoin had been swallowed. Of this amount some was apparently vomited a few hours afterwards and some was withdrawn by gastric lavage. It was obvious, however, that a large amount had been absorbed, although without blood level readings it is impossible to form any idea of the exact quantity. From a consideration of the clinical features of the case it would seem that the chief effect of the drug was on the vestibular nuclei. The raised blood pressure would suggest an effect on other medullary centres. There was complete absence of any evidence of derangement of cortical function. The headache was probably due to the rise in blood pressure. The escape of the other systems from effects of the drug is as would be expected, it being accepted that soluble phenytoin has no deleterious action on the blood, kidneys, liver, or heart. It is also of interest that a major epileptic attack occurred ten days after the overdose was taken—five days after the patient was regarded as having completely recovered.

### Summary

A case of gross overdosage (self-administered) of soluble phenytoin is described. The clinical features consisted mainly of gross cerebellar ataxia, which improved in five days. No specific therapeutic measures were carried out and recovery was good. A major epileptic attack occurred five days after recovery.

I wish to thank Dr S. Locke, physician to the hospital, for his advice, and Dr E. Miles, medical superintendent, for permission to publish this case report.

### REFERENCE

Blair, D. (1939) *Post grad med J* 15 344

The St John and Red Cross Joint Committee have allocated £150,000 out of funds earmarked for the relief of disabled ex-Service men to meet the urgent necessity for more extensive quarters for the nurses at the Star and Garter Home for disabled ex-Servicemen at Richmond. The Star and Garter is one of the homes not included in the national health scheme. Because nearly all the 183 patients are bedridden, or mobile only in invalid chairs, it requires as many as 152 people—nurses, domestic workers and administrative staff—to look after them.

## Medical Memoranda

### Late Recurrence After Marsupialization of Echinococcus Cyst of Liver

The following is a case of echinococcus cyst of the liver recurring 20 years after operative removal. An additional interest lies in the fact that the cyst had become subcutaneous.

#### CASE HISTORY

The patient, a man aged 43, was seen at the out patient department at the end of June, 1947, complaining of a continuous pain in the region of and under the right costal margin. The pain also radiated towards the back. He had first noticed it in January, 1947. He had seen several doctors, and all their investigations had been negative. It was known that for several years past he had been suffering from

Photograph of cyst after removal. The daughter cysts are clearly seen.

neurosis. He had been evacuated to the UK in 1944 for anxiety state, chronic, severe, unspecified. He had settled down well at a psychiatric centre and was eventually down graded to Category B.

He had served in Iraq from 1920 to 1922. While stationed at Edinburgh in 1926 he complained of lack of energy and of pain in the region of the right costal margin. He complained of indigestion, a tightness in the upper abdomen, and regurgitation of food. There was no jaundice or melena. His Wassermann reaction was negative. On examination a solid irregular swelling which moved on respiration was palpable under the right costal margin.

There was a slight increase in the lymphocyte count. A barium meal showed no abnormality. He was thought to be suffering from a carcinoma of the pyloric end of the stomach, and was transferred to a military hospital. There he was given a course of emetine without apparent benefit. A laparotomy was then carried out and a hydatid cyst of the liver was found. From the old notes it appears that the cyst was marsupialized and that the appendix was removed. He made a slow recovery, the wound discharging for many weeks. Subsequently, however, it had remained firmly healed and had not caused any trouble.

After the appearance of fresh symptoms in January, 1947, a barium meal test was carried out in connexion with a medical board and the report was as follows: "The meal revealed a hypertonic stomach, though not amounting to the steer horn type. The mucosal pattern was normal. The finer details of the duodenum were difficult to see owing to the patient's obesity, but it filled readily without delay. The outline was smooth and not deformed. There was some tenderness above the duodenum in the region of the scar. No ulcer niche was seen."

When the patient reported he told me that he was certain his pain was genuine. It had eased off for a while, but had come back and was then mainly localized to the upper end of the scar, where a small swelling appeared at the end of June, 1947, which increased rapidly in size.

On examination I found him to be well nourished. There was a very long right paramedian scar, broad and keloid at its upper extremity, where there was a hard fixed lump the size of a large plum. The skin over the lump was shiny but not hot or red, and it was only slightly tender. A small benign tumour, a chronically incarcerated piece of omentum, or some slow process around an old suture were considered as a diagnosis, the possibility of a recurrence of the hydatid disease was also kept in mind. The straight x-ray film of the abdomen taken five months previously showed no calcification or other abnormality.

The next day, under general anaesthesia, the tumour was aspirated and about 10 ml of a clear colourless fluid was withdrawn. An equal quantity of commercial formalin was then injected. Immediate

examination of the fluid revealed no scolices but some albumin. A transverse incision was then made encircling the tumour and including the needle track. The abdominal cavity was soon entered and was packed off with gauze. The subcutaneous lump was seen to be connected with a large pear-shaped cyst arising from inside the liver and projecting from its middle towards the left and the stomach. A line of cleavage was found and the cyst was shelled out intact. There was considerable bleeding from the liver bed, which was controlled by fibrin foam and a gauze pack. On the third day the pack was removed and the patient made a good recovery.

The report of the pathologist (Major H J Voss) was as follows: "A thick-walled cyst measuring approximately 10 by 7 cm. The wall appears to consist of laminated fibrous material and is 0.5-1.5 cm thick. Inside the cyst can be seen numerous hydatid daughter cysts, most of which had separated from the wall of the cyst. Blood capsules in the endocyst were scanty and scolices of *Taenia echinococcus* were demonstrated with difficulty. Microscopical examination. The wall of the cyst consists of laminated fibrous tissue. The inner layer consists of a cellular hyaline-like material having no specific characteristics, the appearances were those seen in a hydatid cyst of long duration."

The following conclusions may be drawn from this case: (1) Marsupialization, though apparently successful, was followed by a recurrence at the same site. (2) All clinical observations including radiography, were at first negative. Only the fact that the cyst had finally become subcutaneous offered a clue to the true nature of the condition. (3) Vigorous upper abdominal pain as long as 20 years after an operation for hydatid cyst can suggest a recurrence.

I wish to thank the Officer Commanding the 94th British Military Hospital and the DMS British Army of the Rhine for permission to publish this case, also Major H J Voss for the pathological report.

### Formation of Obstructing Band in 21 Days

I previously reported the incidental finding of adhesions causing matting of adjacent coils of small bowel, dense enough to produce intestinal obstruction, that had been formed in 28 days after an abdominal operation (Duff, 1946). The bowel had been found strangulated and severely damaged, and it was reasonable to suppose that an undue amount of lymphatic or haemorrhagic exudation had taken place and that its subsequent organization was responsible.

In the following case there was no damage to the bowel, but obstruction from adhesions arose 21 days after a laparotomy.

#### CASE HISTORY

A woman aged 33 had had an interval appendicectomy performed by another surgeon, from which she had made an uninterrupted recovery. No adhesions had been noted. Exactly 21 days later she was readmitted to hospital complaining of colicky abdominal pain and vomiting, symptoms which had arisen that day. After temporizing for about 12 hours it was obvious that a small bowel obstruction existed, and I performed a laparotomy.

Adhesions were found binding the caecum, omentum, and anterior abdominal wall scar together, the terminal ileum was tightly adherent to the medial side of the caecum. The obstruction was due to a band arising from the caecum, fixed to the posterior abdominal wall, and constricting the ileum about 18 in (45 cm) from its termination. The band was divided, and the patient made another uninterrupted recovery. She has remained well since.

#### COMMENT

The adhesions undoubtedly followed the previous operation which, indeed, could not have been performed in their presence. A band is presumably formed by the gluing together of surfaces and their subsequent pulling apart while the adhesion is still plastic enough to stretch but strong enough not to rupture. Boyd (1947) states that such bands cause obstruction by their subsequent gradual contraction. In the above case a band strong enough to cause small bowel obstruction was formed in exactly 21 days.

### HALLMARKS OF MANKIND

*Hallmarks of Mankind* By Frederic Wood Jones, D Sc, M B, B S FRS, FRCS (Pp 86, 23 illustrations 10s 6d)  
London Baillière Tindall and Cox 1948

Under this title Professor Wood Jones has published his Cambridge Linacre Lecture and an Arris and Gale Lecture delivered at the Royal College of Surgeons. These lectures were designed to embrace the two main contentions for the acceptance of which 'the author has 'striven for thirty years'. The first is that, considered solely from the point of view of structure, man is an extremely primitive type, and the second that, though more primitive in basal structure than the living monkeys and apes, man has his own remarkable structural specializations that distinguish him from all other mammals and appear to be his very ancient hallmarks. Professor Wood Jones argues his case with characteristic force and verve, though to some it may seem that certain slain lions are disinterred for belabouring.

In the first lecture Professor Wood Jones states the case for his opinion that the human stock was derived from the main primate stem separately from and probably prior to the emergence of the anthropoid apes, and even, it is suggested, at a pre-catastrophe stage. As Professor Wood Jones rules out of consideration the South American monkeys in the question of human phylogeny, and as he denies primate status to the lemurine group, he is left with an unspecialized tarsoid as the probable primate ancestor of man. To paraphrase Dr Gaylord Simpson, Professor Wood Jones 'wishes to derive man—or perhaps wishes man had been derived—from a vaguely remote early tertiary source independent of the origin of monkeys and apes'. It would be rash, in view of our restricted knowledge of primate fossil material, to be dogmatic in denying this possibility, but in the reviewer's opinion the weight of available evidence palaeontological, embryological, and morphological, appears to be against its acceptance.

In his second lecture Professor Wood Jones discusses certain structural features (among others, the peculiar relationship of the maxilla to the premaxilla, certain dental characters, and the great toe) which can be regarded as distinctive of man. These features are the hallmarks. In silver, however, hallmarks are not inherent in the metal, they are impressed by authority, have been known to be counterfeited, and are limited to a relatively small group of particulate symbols. In a biological system the symbols in the form of morphological characters, are numberless—they are in constant intra- and trans-individual flux, and they vary from individual to individual in a manner that frequently defies arbitrary limits and definitions. Whether Professor Wood Jones's particular selection of a few of these characters as hallmarks is accepted or not will depend on the reader's willingness to regard these few characters, against the background of the totality of morphological characters of man, as the really significant ones in establishing our concept of the human species.

The lectures are attractively written, but there are a number of trivial misprints, and the absence of a bibliography is to be regretted.

### PSYCHIATRIC RESEARCH

*Psychiatric Research* By Cecil K. Drinker, J. Folch, S. Cobb, H. S. Gasser, W. Penfield, E. A. Strecker. Papers read at the dedication of the Laboratory for Biochemical Research, McLean Hospital, Waverley, Massachusetts, May 17 1946. Harvard University Monograph in Medicine and Public Health 9 (Pp 113, illustrated \$2.00 or 11s 6d) Massachusetts Harvard University Press London Geoffrey Cumberlege (Oxford University Press)

This slim dedicatory volume is a testimony to the great changes that have come over psychiatry in the last quarter of a century. The mental hospital doctor is no longer the mere custodian of the mentally sick and occasionally the inspired observer of

mental phenomena. Advances in neurology, biochemistry and dynamic psychology have entirely altered psychiatry and have raised the morale of the physicians engaged in what was formerly an unrewarding specialty. It is true that the volume shows what liberal endowment can do to stimulate science but we must not forget that it needs ability of a high order to make use of such liberality. The essayists of the volume are all leading transatlantic psychiatrists.

After an opening account of the McLean Hospital and the work of pioneers such as Wynnans and Carles, Dr Jordi Folch discusses biochemical problems of brain function, then he rightly emphasizes the significance of the absence of lymphatics and the low vasomotor lability of the neural tissue, and above all its high oxygen consumption and the significance of the blood-cerebrospinal fluid barrier. This barrier indicates that there is a very specialized neural metabolism at the capillary level, and one in which glucose is directly utilized without the intervention of either insulin or pituitary hormone. Glutamic acid alone among amino acids can sustain the respiratory action of brain tissue *in vitro* (an important fact in view of the alleged effect of this amino acid on mental retardation). He discusses the function of the astrocytes in limiting capillary permeability and probably acting as selective and retarding agents, and he considers at length the special role of brain lipoids and the paradoxical facts about oxygen consumption at different ages.

Dr Stanley Cobb considers in a more general manner the question of integration of mental and psychiatric problems as seen in the Massachusetts General Hospital. He takes as a special problem of integration the condition known more in America than here as neuro-circulatory asthenia and distinguishes it from anxiety neurosis. In many ways this is a central problem in the study of neurosis, where psychical events belong more to experience than to body structure and function. Hence the paradoxical nature of many of the features of these symptom complexes. He rightly concludes that a pluralistic view is necessary before we can fathom each of the personal problems presented to the physician.

Professor Wilden Penfield discusses psychical seizures, and forms from evidence provided by brain surgery and the electro-encephalogram the substrate of such mental events as hallucinosis, petit mal, stereotyped behaviour, etc. Here, perhaps, we see the gradual closure of the no man's land between the mental and the physical. Dr E. A. Strecker's essay is a plea for psychosomatic unity in all psychiatric practice and thinking. His treatment of the subject is somewhat diffuse and perhaps needs a more philosophical approach than the author dares to adopt. This volume should interest aspirants to psychiatry and instruct those who have hitherto regarded the subject as either unscientific or a playfield for those of easy virtuosity.

EMANUEL MILLER

### EARLY DIAGNOSIS

*Diagnosis in Daily Practice* An Office Routine Based on the Incidence of Various Diseases. By Benjamin V. White, M.D. and Charles F. Geschickter, M.D. (Pp 693, 360 illustrations £4 10s) Philadelphia and London J. B. Lippincott 1948

The main theme of this book is sufficiently unusual to warrant widespread attention. The authors are impressed by the relatively small number of common diseases which are responsible for the bulk of disability and death, a circumstance clearly demonstrated by a section on vital statistics early in the book. They therefore emphasize the need for prompt recognition of these major diseases, particularly in their pre-symptomatic stages, when they are most susceptible to treatment. This goal can be fully attained only by means of routine medical examinations. The authors have worked out a plan of history taking, clinical examination, and six simple laboratory investigations which is designed to draw attention to the major diseases. The routine examination of people not complaining of disability can so easily prove a barren labour that this guide is most useful.

The largest part of the book is on the diagnostic implications of various symptoms, and there are many tables showing what additional clinical and laboratory evidence is necessary for the physician to proceed from symptom to correct diagnosis.

Here the book is marred by two faults. First, although it is intended to serve as a practical reference for the doctor in general practice, it includes much material on the elicitation of common physical signs of which no medical man should be ignorant. To give one example of many there are two pages on methods of eliciting tendon reflexes, including diagrams on how to obtain knee-jerks, ankle clonus, and plantar reflexes. Secondly, the authors have been unable to resist mentioning the rare diseases which may be responsible for the symptoms under discussion. As a result, the lists of diseases under many symptoms are of formidable length, and by comparison the accompanying discussions are jejune. It seems a pity that an objective so admirable as the early diagnosis of the major diseases should be obscured by the inclusion of redundant and irrelevant matter.

In spite of these drawbacks this is a brave attempt to raise the level of medical practice and fully deserves study particularly by those doctors responsible for routine examinations. The book is beautifully produced, and the numerous diagrams, tables, and photographs are models of clarity.

SIDNEY TRUELOVE

## TEACHING HEALTH

*Education and Health* By R. Gamlin, MB, BCh, MRCS, L.R.C.P., M.Hyg., and D.P.H. (Pp. 372, 69 figs. 12s. 6d.) London: James Nisbet and Co. 1947.

This book consists of a series of essays written for parents and teachers. The first seven chapters are on the mind, its development from our earliest ancestors to the intelligent thinking of modern man. In the first two chapters the author explains clearly the persistence of superstition and many of the defects of thinking still with us, the use of deduction and analogy rather than induction and intuition, the failure to control feeling and striving, wishful thinking, false cause, *non sequitur*, special pleading and begging the question. The remedy for all this is wide and critical reading, the development of powers of observation, and the mastery of words spoken and written. Should we not all study Sir Ernest Gowers's *Plain Words*? The third chapter is on the subconscious mind, which can be filled with complexes stirred by conflicts and disturbed by repressions; the author seeks to show how teachers and parents can help the child to maintain a healthy balance between the conscious and unconscious mind. In these three chapters he develops facts and hypotheses upon which the teacher should base his teaching to train minds free from superstition, fearless in facing facts, observant and critical, possessed of a mastery of words and purged of conflicts, complexes, and repressions. In a word, masters of their destiny and their thoughts.

In the fourth chapter he considers the workings of the human mind and its components, the instinctive or conscious urge, the feeling developing to sentiments and senses, the intellect controlling and directing. Combine these three and you have character. The teacher must seek to instil the will to direct urge and feeling towards a social conscience, so that conduct shall be guided by ethical right rather than for praise, reward or pleasure. So we learn in the fifth and sixth chapters of maladjustment and delinquency and the opportunities for child-guidance both in the home and at school. In Chapter 7 the author gives a useful account of backwardness.

The remaining chapters suffer somewhat from lack of sequence of thought. Chapter 8 is a valuable account of the wave theory of sound; in Chapter 9 the author shows how this knowledge can be applied by the pure-tone audiometer and the gramophone audiometer to the problems of schools; and Chapter 10 is an account of colour blindness. But the remaining chapters on "British Fare throughout History," "Dietetics: The Quest for Pure Milk," "The Care of the Teeth," "Rheumatism in Children," "Parasites of the Skin," "Pioneers in Immunity," and "Immunization against Diphtheria" suffer from being over-simplified accounts of complex subjects. Yet the book must be regarded as a courageous effort to present scientific matter in readable form for people who have responsibilities for the upbringing of children, and its wide reading should bring many benefits.

FRASER BROCKINGTON

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Clinical Electrocardiography* By D. Scherf, M.D., F.A.C.P., and L. J. Boyd, M.D., F.A.C.P. 3rd ed. (Pp. 435. 3s.) London: Heinemann. 1948.

Illustrated with many electrocardiographs.

*A Short Practice of Midwifery for Nurses* By H. Jellett, B.A., M.D., F.R.C.P.I., and J. B. Dawson, K.B.E. M.D., B.S., F.R.C.S., F.R.C.O.G., F.R.A.C.S. 14th ed. (Pp. 459. 12s. 6d.) London: J. and A. Churchill. 1948.

A practical illustrated manual for nurses and midwives.

*A Short Practice of Surgery* By H. Bailey, F.R.C.S., F.A.C.S., F.I.C.S. FRSEd., and R. J. McNeill Love, M.S., F.R.C.S., F.A.C.S., F.I.C.S. 8th ed. Part I. (Pp. 224. 52s. 6d. the set of 5 parts.) London: H. K. Lewis. 1948.

The parts of this edition are not sold separately.

*A Pocket Medicine* By G. E. Berumont, M.A., D.M., F.R.C.P., D.P.H. 2nd ed. (Pp. 208. 9s.) London: J. and A. Churchill. 1948.

An introduction for medical students.

*A Textbook of Gymnastics* By K. A. Knudsen. Vol. II. (Pp. 204. 12s. 6d.) London: J. and A. Churchill. 1948.

Exercises mainly for the limbs are described.

*Recent Advances in Obstetrics and Gynaecology* By A. W. Bourne, M.B., B.Ch., F.R.C.S., F.R.C.O.G., and L. H. Williams, M.D., M.S., F.R.C.S., F.R.C.O.G. 7th ed. (Pp. 326. 21s.) London: J. and A. Churchill. 1948.

The text has been extensively revised to bring it up to date.

*Hygiene* By J. R. Currie, M.A., M.D., LL.D., D.P.H., F.R.C.P.Ed., and A. G. Mearns, M.D., B.Sc., D.P.H. FRSEd. 3rd ed. (Pp. 724. 35s.) Edinburgh: E. and S. Livingstone. 1948.

Includes new material on statistics, milk legislation, 'prefab' design, and aircraft regulations.

*Human Histology* By E. R. A. Cooper, M.D. 2nd ed. (Pp. 431. 27s. 6d.) London: H. K. Lewis. 1948.

An illustrated manual for medical students.

*Recent Advances in Anaesthesia and Analgesia* By C. Langton Hewer, M.B., B.S., M.R.C.P., D.A. 6th ed. (Pp. 380. 21s.) London: J. and A. Churchill. 1948.

Contains much new material, including a chapter on muscle relaxants.

*Dermatology and Venereology for Nurses* By J. H. Stokes, M.D., and J. B. Taylor, B.S., R.N. 4th ed. (Pp. 416. 17s. 6d.) London: W. B. Saunders. 1948.

A textbook for training and qualified nurses.

*Human Ecology* By T. Robertson. (Pp. 534. 21s.) Glasgow: MacLellan. 1948.

The author brings his training in biology and medicine to bear on the problems of sociology.

*The Truth about the Stork* By E. F. Griffith, M.R.C.S., L.R.C.P. (Pp. 136. 6s.) London: H. K. Lewis. 1948.

An account of sex and reproduction for children.

*Chemistry in Nursing* By R. E. Neal. (Pp. 564. 24s.) London: McGraw Hill. 1948.

A textbook of inorganic and organic chemistry for student nurses.

*Manual of Determinative Bacteriology* By R. S. Breed et al. 6th ed. (Pp. 1,529. 82s. 6d.) London: Baillière, Tindall and Cox. 1948.

Details of the morphology, habitat, and culture of micro-organisms.

*A History of the Heart and the Circulation* By F. A. Willius, M.D., M.S., and T. J. Dry, M.A., M.B., Ch.B., M.S. (Pp. 456. 40s.) London: W. B. Saunders. 1948.

A historical study with biographies of leading cardiologists.

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 2 1948

## A GUIDE TO THE Rh FACTOR

Few laboratory discoveries of recent years have been fruitful so quickly in the clinical field as the recent work on blood groups. During the war the blood transfusion services enjoyed close personal association with many clinicians and scientists who, but for the shortage of more junior staff, would probably not have engaged in such work. Consequently the discovery in 1940 by Landsteiner and Wiener of the Rh factor and their work on its significance in intragroup transfusion reactions, followed in 1941 by the elucidation by Levine and his co-workers of the important part it played in obstetric and neonatal pathology, came at a time when the medical and scientific world was well prepared to receive this new knowledge. The Medical Research Council appealed for help in the collecting of sera and clinical data early in 1942, and the essential facts were quickly confirmed by the late G. L. Taylor and by P. L. Mollison. These MRC workers were later joined by R. R. Race, and with the generous help of clinicians and pathologists throughout Great Britain they were enabled rapidly to extend the field of knowledge both on the clinical side and in relation to Rh antigens and antibodies. The period during the war when the research was carried on at Cambridge was of the greatest value, for the serological work benefited from Professor H. R. Dean's wide knowledge of antigen-antibody reactions, while the genetic studies were subjected to that penetrating scrutiny by Professor R. A. Fisher which culminated in the brilliant analysis and synthesis which has so greatly illuminated the whole subject. The end of the war saw the removal of the MRC unit to London and a resumption of the clinical collaboration with P. L. Mollison which has been so fruitful earlier. The continued interest of the medical and scientific world in Rh problems is seen in the prominence given to it at conferences and in the medical press, and the publication of *The Rh Blood Groups and their Clinical Effects*, by P. L. Mollison, A. R. Mourant, and R. R. Race,<sup>1</sup> will be welcomed in this and other countries. This authoritative monograph by the workers who first contributed to research in Great Britain provides all the most up-to-date information on this complex and controversial subject and lays down simple rules for the guidance of laboratory and clinical workers which should do much to remove confusion and to standardize practice in this field.

The work is conveniently divided into three sections: (1) the serological analysis of the Rh groups, (2) clinical considerations of diagnosis and treatment, and (3) indica-

tions for and technique employed in Rh tests. After a brief historical introduction Race gives a clear account of the Rh antigens and antibodies. He uses throughout Fisher's notation as "the only one capable of fully designating the genes, compound genes or chromosomes, and the genotypes." This enables him to make it clear at the outset that Rh-positive means the possession of Fisher's antigen D and that all those who have only the allele d are Rh-negative, despite the presence of any other antigen. Having mastered this fundamental distinction, the reader is introduced to the other linked Rh genes, C or c, and E or e, and so to the resulting eight Rh complexes. The frequencies of the commoner gene combinations and the approximate error in assessing the genotypes are given—points of some importance in advising parents about their chances of having a normal infant after one affected by haemolytic disease. The more advanced subdivision of the elementary antigens C, c, and D follows, but this section will prove difficult to the uninitiated reader, nor is it rendered easier by inconsistencies—for example, on page 16 there are listed twelve Rh chromosomes, giving rise to 78 genotypes, but Table IV gives eight Rh chromosomes, including C<sup>w</sup>De but excluding others known to exist (C<sup>w</sup>de, Cde, CD<sup>w</sup>e, etc.). It also seems arbitrary to base Table V solely on the data of Table IV and one collection of 2,000 samples of blood when other information was available.

Dr Race distinguishes the two types of Rh antibodies as "saline agglutinating" and "albumin agglutinating," the latter term superseding "incomplete," "blocking," or "hyperimmune" antibody. Representative examples of haemolytic disease due to the rarer Rh antibodies in pure form are given and help to clarify the subject. After a brief mention of the use of Rh tests in cases of disputed paternity and in ethnology this section concludes with a discussion of the genetical basis of the Rh groups in so clear and simple a fashion as to be within the grasp of any serious student. A misprint mars the second calculation on page 25. R<sub>1</sub>R<sub>0</sub> is given as CDe/cde instead of CDe/cDe, the penultimate paragraph about  $\chi^2$  also does not make sense in the present form.

In his section Mollison describes very clearly the ways in which iso-immunization is brought about. All clinicians who prescribe blood for therapeutic purposes should study the paragraphs on the importance of repeated transfusions and the methods of recognizing and distinguishing the various grades of haemolytic reaction. The greater part of this section is devoted to iso-immunization in pregnancy. The detection of sensitization, the interpretation of the findings, and the effects upon the foetus are all lucidly expounded, but the subject of nuclear jaundice deserves fuller consideration. The differential diagnosis of haemolytic disease is fully discussed and should encourage further study of the pathology of stillbirths and neonatal deaths. Details of the morbid anatomy and histology are not given but the interested reader has the admirable account by Edith Potter<sup>2</sup> to fall back on. The incidence of maternal toxæmia is higher in the mothers of affected infants, and it is surprising that in the paragraphs about the management of pregnancy when an affected infant is expected no mention is made of toxæmia being the most important reason for therapeutic abortion. In view of the guarded

<sup>1</sup> Medical Research Council Memorandum No. 19, 1948. Published by H.M.S.O. London. Price 1/6.

<sup>2</sup> Potter E. L. *Rh: Its Relation to Congenital Haemolytic Disease and Intra-group Transfusion Reactions*. London: H. K. Lewis, 1947.

statements about prognosis it is difficult to see on what other ground abortion would be recommended, yet this is a problem about which the specialist is frequently consulted. Otherwise the advice on induction of labour, on confirmation of the haemolytic disease, and on when to transfuse is given with the greatest clarity and precision and should become a standard guide to practice.

Mollison's directions for transfusing infants by various routes and for exchange transfusion will be appreciated, and we commend his advice on the instruments to be used. Fine ophthalmic knives and forceps have proved suitable and should be available in most hospitals. The importance of avoiding sensitization of Rh-negative females by the parenteral administration of Rh-positive blood is emphasized, and the importance of routine antenatal Rh testing as a means of obviating this risk and at the same time conserving Rh-negative blood for those who ought to have it is fully explained. The risks of calling Cde/cde and cdE/cde persons Rh-positive are discussed. This danger still needs stressing, although Cappell drew attention to it as early as 1944 and pointed out that such persons are liable to iso-immunization against D. They must be considered Rh-negative as recipients, but should not be used as Rh-negative donors. Mollison concludes with some remarks on the advice which should be given to parents of affected children about future pregnancies. The 3 to 1 preponderance of homozygous fathers is seen in families where the second child is affected, but with families greater than two the proportion of heterozygous fathers is certainly higher. This exposition will, however, be of the greatest assistance to practitioners who have the difficult task of explaining to parents the loss of an affected child and the outlook for the future.

Laboratory workers who have to carry out the technical procedures will find Mourant's section of great practical value. He gives an admirably lucid account of how and when cells and serum should be tested. Clinicians are reminded of their obligation to maintain supplies of sera by furnishing generous samples of blood whenever a suitable test reagent is encountered. This cannot be stressed too strongly, for without these supplies the work would come to an end, and Mourant rightly points out that at present a few enthusiastic medical officers are providing sera for the whole country. In the discussion on the recognition of individual antibodies the footnote to Table XII is a little misleading, for if anti-C contains albumin-agglutinating anti-D it will react positively in albumin with cDe/cde cells. The same applies to anti-E, and Table XII will not therefore indicate the total antibody content of the serum.

Taken as a whole, this monograph is a fine production. It presents what is now accepted in Great Britain as the best practice in this field irrespective of its origin. Readers new to the subject might be excused for thinking that the only research on Rh in Great Britain had been done by the M R C workers, since there are few references to other British authors. Those who are engaged in the work or who have followed the literature, however, will realize that this valuable memorandum incorporates many ideas which first appeared in print elsewhere and which are now so generally accepted as to require no acknowledgment.

## INJURIES CAUSED BY COLD

The literature of the major cryopathies—frostbite, trench foot, and immersion foot—is now enormous, but happily for the general student of the subject the greater part of it consists of clinical descriptions containing no new observations, descriptions of methods of treatment, almost all of them valueless, and pathological guess-work better left unread. Nevertheless the mere bulk of the published work in a variety of languages testifies to the great importance of the subject, especially but not exclusively in time of war. Almost all the papers of any value have been published during or immediately after the two world wars, though much of historical interest was written during the Napoleonic and Crimean campaigns. Although many guesses, some good and some bad, had been made about the pathology of frostbite and trench foot, the first step to a clear understanding was the work of Rotnes and Kreyberg,<sup>1</sup> who in 1932 performed experiments that suggested that the application of carbon-dioxide snow to rabbits' ears produced blockage of the vessels with red cells and consequent necrosis. The suggestion appears to have escaped notice until attention was drawn to it by Raymond Greene<sup>2</sup> in 1943. He approached the problem by a different experimental route and was able to demonstrate histologically that freezing even to solidification does not necessarily result in necrosis and that the changes which occur are, first, vasoconstriction, secondly, vasodilatation, thirdly, structural damage to arterioles, resulting in transudation and perivascular oedema, and, fourthly, a consequent "silting up" of the vessels by agglutinated red cells, followed by necrosis of tissue. He also showed that thrombosis does not appear except occasionally as a later secondary change, and that the deposit of crystals in the cells, regarded by Sir Thomas Lewis as the cause of the necrosis, is, in fact, harmless in itself. Greene's results in true frostbite were confirmed by Lange and Boyd<sup>3</sup> and by others, and were shown to be equally true of trench foot.<sup>4</sup> It is interesting to observe by what diverse experimental methods the same conclusions have been reached. Rotnes and Kreyberg used intravital staining, Greene direct histological examination and photomicrography, Lange and Boyd the injection of fluorescein and observation by long-wave ultraviolet rays and by capillary microscopy.

Intravascular agglutination having been established as an essential part of the pathology, it was a short step to a trial of heparin in the treatment of frostbite. Lange, Wiener, and Boyd<sup>5</sup> and Lange and Loewe<sup>6</sup> produced experimental frostbite in volunteers. The latter found that the injection of heparin in the amount required to keep the clotting time between 25 and 60 minutes completely prevented necrosis, whereas all controls developed areas of necrosis approximately 1 cm in diameter and from 3 to 5 mm in depth. Immediate injections of heparin afforded complete protection, but treatment given up to 24 hours after exposure produced results almost as good.

<sup>8</sup> *Surg. Gynec. Obstet.* 1943 77 561

<sup>9</sup> *J. Bone Jt. Surg.* 1942 24 785

Two cases of severe accidental frostbite were treated, one six hours after an eight-hour exposure to a temperature of  $12^{\circ}$  to  $13^{\circ}$  F ( $-11^{\circ}$  to  $-10.5^{\circ}$  C) and one ten hours after a twelve-hour exposure to a temperature of  $14^{\circ}$  to  $18^{\circ}$  F ( $-10^{\circ}$  to  $-8^{\circ}$  C). In neither case did serious damage ensue, though the authors point out that there can be no certainty that gangrene would have occurred without treatment. It seems highly probable that it would have done so.

Lange, Wiener, and Boyd gave careful consideration to Greene's suggestion<sup>7</sup> that parts injured by cold should be kept cool. Small areas of the skin of three volunteers were frozen by means of a metal capsule kept at  $-30^{\circ}$  C for half an hour. Each received at least five exposures. They received either no treatment at all or warming for 24 hours without heparin, or immediate treatment for seven days with heparin, or treatment with heparin for seven days after a delay of 24 hours, or treatment with heparin for seven days after 24 hours of treatment by warming. From this experiment it appeared that warmth was definitely harmful. Heparin was of value even when its administration was delayed for 24 hours. On the other hand, in another experiment it was found that cooling with an ice-bag in the interval between exposure and treatment with heparin resulted in a larger lesion than in the controls. Blister formation was completely inhibited by cooling, but occurred immediately afterwards. It may be argued that it is extremely difficult to produce exactly similar lesions experimentally and that the number of the experiments was for this reason too small. It is possible, also, that cooling for a longer period, during which time the damaged vessels would have had more time to heal, might have been beneficial. Nevertheless the experiment is in accord with the findings of Davis and his colleagues,<sup>8</sup> who treated a number of cases in consultation with Greene, and concluded that cooling of the affected parts, though reducing blistering, did not affect the development of gangrene. Another view is taken by Webster, Woolhouse, and Johnston,<sup>9</sup> who found that dry cooling of affected parts relieved the constant burning and bouts of stabbing pain characteristic of chilled limbs, caused subsidence of the swelling and resorption of blisters, and even prevented what appeared to be impending gangrene. In this series cooling was continued for from 6 to 21 days.

All authorities are now agreed that warmth is harmful. Disagreement continues about the degree of cooling to be recommended. If, as seems possible, those who have advised temperatures round about  $5^{\circ}$  C have overstated the case, they may at least gain comfort from having drawn attention to the undoubted evils of rapid warming, a practice not yet entirely dead. The use of heparin may in any case make the question of temperature during treatment one of only academic significance.

### REPORTS ON VAGOTOMY

In a recent review of the treatment of peptic ulcer by resection of the vagus nerves Alvarez<sup>1</sup> lists over 200 papers going back for 60 years. It is still too soon to pass judgment upon the operation, for current discussions show that there are differences of opinion, and certain problems

remain unanswered. The first of these is the scope of the operation. Is vagotomy equally applicable to gastric, duodenal, and anastomotic ulcers, or should its use be confined to the two last types only? Some remarks upon vagotomy for gastric ulcer have recently been made by Dragstedt and Harper.<sup>2</sup> The former is responsible for the present enthusiastic revival of the operation, which was envisaged by Sir Benjamin Brodie in 1814 and practised with success over 20 years ago. He considers that a partial or subtotal gastrectomy should be performed for any ulcer in the antrum or the body of the stomach. He commends vagotomy as a useful procedure for ulcers high on the lesser curvature, even if malignancy is suspected. For these lesions a total gastrectomy is the only alternative. The mortality of this operation is from 10 to 30%, and in malignant cases the prognosis for ultimate survival is poor. If vagotomy is followed by the prompt healing of the ulcer not only is malignancy unlikely but the patient is saved from a hazardous ordeal.

The second question is, Should the nerves be cut above the diaphragm or is section at abdominal operation sufficient? The latter method is now generally adopted because it enables the lesion to be inspected, and any short circuit that may be thought necessary can conveniently be done. Moore,<sup>3</sup> however, challenges this view, and considers that in possibly 10% of subjects it is impossible to cut all the fibres by the abdominal operation. Walters and his co-workers<sup>4</sup> have studied the anatomy of the vagus nerves and support this opinion. They found in 8 out of 100 subjects the vagi had no consistent course and the oesophageal plexus failed to form common trunks. On this evidence it is difficult to be certain that every fibre can be cut by an operation below the diaphragm. Grimson and his colleagues<sup>5</sup> also used the thoracic route in over 60 cases so as to ensure complete division of the nerves in all cases.

Most surgeons with experience of this operation have found that a gastro-enterostomy appears to be required in certain cases. Here again Moore holds contrary views. As he says, the placing of jejunal mucous membrane in the stomach has been a source of trouble ever since the introduction of posterior gastro-enterostomy. He also points out that the latter operation itself may assist the healing of ulcers in a proportion of cases. Moore attributes the absence of any indication for gastro-enterostomy in his cases to his most careful post-operative regime. Gastric suction is kept up for 48 hours, and only small amounts of fluid are allowed for the first three days. The diet is then cautiously increased, the stomach being aspirated daily. Should any significant residue form, the diet is reduced. It appears that the ineffectual gastric peristalsis is able to manage small quantities of solid food better than liquids.

Earlier reports suggested that the operation of vagotomy carried very little risk to life. Fatalities, however, are recorded, and a consideration of their causes reveals some interesting features. During the operation sudden death may occur when the nerves are gripped prior to section, as has been reported by Weeks and others.<sup>6</sup> In the immediate post-operative period gastric retention may cause much anxiety, and Grimson and his colleagues<sup>5</sup> have reported a death from rupture of the stomach on the seventeenth day. Although the vagus nerves are not thought to carry sensory fibres, there have been several reports of patients dying from a painless perforation many months after

section of the nerves. For the proper evaluation of vagotomy two things are necessary: one is the passage of time, and the second, as Johns and Grose<sup>7</sup> stress, is the comparison of groups of patients treated by different methods but all having some clinical and pathological uniformity. So far experience shows that in some cases the immediate results can only be described as dramatic. It remains to be seen, however, if the gastric acidity, mobility, and secretion will return to normal in man, as was found by Vanzant<sup>8</sup> to be the case in dogs.

### PROLONGING PENICILLIN ACTION

Until recently the most useful of many devices for obtaining a greater effect from a given dose of penicillin have been the oil-and-beeswax base and *p*-aminohippuric acid. The disadvantage of oil preparations is that only those containing beeswax give a really prolonged action, and this substance is apt to produce unpleasant local effects. The necessity to inject *p*-aminohippuric acid intravenously severely restricts its field of usefulness. This objection does not apply to another substance which also blocks the renal excretion of penicillin, though by a different mechanism: caronamide (4'-carboxyphenylmethane-sulphonamide) can be given in solution by mouth. The effects of this drug have now been extensively investigated in the U.S.A. both in animals<sup>1</sup> and in normal human subjects.<sup>2,3,4</sup> It has also been shown experimentally that the efficacy of penicillin is increased by raising its concentration in the blood in this way.<sup>5</sup> The latest pharmacological study by Boger and his colleagues<sup>6</sup> may explain some of the minor discrepancies in earlier reports, since they find that response varies in different individuals, they therefore recommend that large doses should be controlled by estimations of the caronamide blood content. This should be 15 mg per 100 ml in order to double the penicillin concentration; it can be considerably higher without producing ill effects. To produce this level of caronamide it is necessary to give 3 g three-hourly or 4 g four-hourly, there is some evidence that in older patients a smaller dose will achieve the same effect, owing to reduced renal efficiency.

Most of these reports are more concerned with the higher penicillin concentrations attained during the first three hours after a dose of caronamide than with the degree of prolongation of a therapeutic blood level which can be secured. That there must be such prolongation is obvious. According to F. H. King and his co-workers<sup>7</sup> there is still as much as 10 units per ml of penicillin in the blood of patients also given caronamide three hours after a single dose of 1,000,000 units, as compared with only about one-fifth of this amount in controls. Loewe and his colleagues<sup>8</sup> gave caronamide to patients with subacute bacterial endocarditis due to exceptionally resistant bacteria, together with penicillin in doses varying from 1 to 20,000,000 units daily by continuous intravenous infusion. The increase in the penicillin concentration in the blood varied from two- to seven-fold. The highest level recorded is 90 units per ml,

if such levels have to be maintained this is certainly the best means of doing so.

Loewe and his colleagues<sup>9</sup> have also devised a base containing gelatin, dextrose, and a vasoconstrictor from which penicillin in solution is absorbed slowly. Ercoli and his fellow-workers<sup>10</sup> claim that a very prolonged effect can be obtained with a preparation of potassium penicillin in vegetable oil also containing adrenaline, and Cohn and Kornblith<sup>11</sup> have had good results in treating gonorrhoea with a single dose of this material. Another new development is the use of relatively insoluble penicillin compounds. Whether aluminium penicillin, reported by Reid<sup>12</sup> to be more effective when given at long intervals to experimentally infected mice, has any future remains to be seen. There is more detailed information<sup>13,14</sup> about procaine penicillin (an equimolecular chemical compound of the two substances), this has a low solubility and is administered as a suspension in sesame or cotton-seed oil without beeswax. A single large dose of penicillin in this form may produce an assayable blood level for 48 hours or even longer—though individual response seems to vary greatly—and cases of pneumonia have been successfully treated by the administration of a single dose. This is the greatest degree of prolongation of effect yet recorded, and the method should have many valuable applications if further experience reveals no disadvantages.

### TOXICITY OF STILBAMIDINE

"Stilbamidine," which has been extensively used in the treatment of leishmaniasis and also in babesiasis, has also been found to give some relief to patients with multiple myelomatosis.<sup>1</sup> A number of workers have investigated the toxic properties of the drug. Animal experiments have been described by Seager and Castelnovo,<sup>2</sup> who observed degenerative changes in the liver and kidney: necrosis in the liver affected sometimes the peripheral and sometimes the central zone, and in the kidney there was cloudy swelling of the convoluted tubules. The liver and the kidney, however, are not affected in man. Arai and Snapper<sup>3</sup> point out that no clear evidence has been published of renal and hepatic damage in cases of kala-azar treated with freshly prepared stilbamidine solutions, and that they found no signs of liver damage due to stilbamidine in five patients with multiple myelomatosis who died, despite the much larger doses used in this condition than in kala-azar.

A toxic effect which does occur in man was described by Napier and Sen Gupta,<sup>4</sup> and has been further discussed by the latter<sup>5</sup> and by Kirk and Henry.<sup>6</sup> This is the appearance of anaesthesia over the areas supplied by the sensory branches of the fifth nerve some two and a half to five months after treatment. There is numbness, formication, and itching; the sensation of light touch is lost, but pain, temperature, and pressure are unaffected. It is suggested that this neuropathy is due to toxic degeneration of the principal sensory nucleus of the trigeminal nerve. There is no danger to life, and the condition slowly disappears. The symptoms are not made worse by further stilbamidine injections.

The Croonian Lectures on "Prefrontal Leucotomy" will be delivered by Dr R. D. Curran, F.R.C.P., before the Royal College of Physicians of London, Pall Mall East, S.W., on Tuesday, Oct. 12, and Thursday, Oct. 14, at 5 p.m.

## BRITISH ASSOCIATION

## 110th MEETING AT BRIGHTON

A common theme running through many of the addresses and discussions at the 110th meeting of the British Association, held at Brighton from Sept 8 to 15, was the problem of world food production with reference both to requirements and to the scheme of tropical development now in progress in Central Africa. Secondly, there were a number of contributions more specifically of medical or biological interest, and, thirdly some few others of sufficient interest or importance to deserve mention on more general grounds.

## World Food Requirements

SIR HENRY TIZARD in his presidential address, suggested that the danger of the present position in regard to food supplies was not fully realized, and quoted the effect of malaria control in British Guiana in illustration of the connexion between preventive medicine and world population. He said:

People remember only too well the apparent over-production of food in the 1930s and forget or do not know that since then the population of the world has increased by some 300 million people. A single example of what is now happening, and will probably happen on an ever increasing scale, will help to illustrate the problem. Malaria has always been one of the most potent instruments of population control. British Guiana has a population of roughly 400,000 which it is probable has remained stationary for the last 20 years. Two thirds of the population used to live under conditions of severe endemic malaria. The birth rate was low, and the infantile and adult mortality rates high. Malaria is now rapidly disappearing from the colony. In a suburb of Georgetown the death rate was equal to the birth rate during the years 1938-44 inclusive, and the average infantile mortality was about 250 per 1,000. DDT control was introduced in July, 1945. By the end of 1947 the birth rate had doubled, and the infantile mortality rate had dropped to 67 per 1,000. The population is increasing by 10% annually. As the new methods of preventive medicine spread—and that there will be many more to come no one can doubt—we must expect the world population to grow at an even faster rate than it has done in our lifetime unless famine intervenes. It will grow particularly in parts of the world that already have a high density of population, such as India where the population is now increasing by five million people a year, and Egypt where there are already 2,000 people to every square mile of cultivated land, and where it pays to have children.

In a later section of his address discussing tropical African development he referred to the chaos and misery which could result 'unless the prevention of disease among plants and animals and all other scientific problems of the supply of food, are studied on the same kind of scale by men of similar calibre as are the problems of human health'—a compliment indeed to the exponents of tropical hygiene.

In somewhat similar vein it was pointed out by Sir JOHN RUSSELL in the section of agriculture that African development must lead to a higher standard of living and a rising population and so to a greater demand for millet, the chief Central African grain food for which science has done singularly little as yet. In the section of geography Dr R. J. H. CHURCH put the case for a colonial institute, operating as part of one of the three principal universities which would undertake or be in touch with colonial research in all or most branches of knowledge. He suggested also that if the French and the Dutch both had good colonial atlases then Britain should have one too, and that using air photography, the Directorate of Colonial Surveys at Teddington should be able to produce a satisfactory atlas within a reasonable period. Finally, Dr F. J. MALINA of Unesco, indicated the scope of international research contemplated as a preliminary to any serious development of the tropical Amazon.

Referring to consumption, Professor A. FLEISCH of Lausanne, described a wartime and post war nutrition survey in Switzerland in which blood counts were used as one index. Whereas a reduction in basic ration from 2,160 to 2,000 calories for an adult in light employment had been followed by only minor changes in the number of red cells, there was a sharp fall after a further reduction to 1,800 calories.

## Human Blood Groups

A discussion on human blood groups was jointly held by the sections of zoology, anthropology and physiology. Dr J. A. FRASER ROBERTS recalled that blood groups were among the

exceedingly few common and simply inherited human traits and that their practical importance and consequent large scale testing permitted applications to geographical and racial variations without parallel in other living forms. Dr R. R. RACE pointed out that the seven recognized systems of blood groups made over 20,000 recognizably different combinations; in England, the commonest having a frequency of 2%, 'while the calculated frequency of the rarest is so low that it may never have formed the blood of an Englishman'. Dr C. D. DARLINGTON summarized the evidence for connecting the distribution of the O blood group in Europe with the Th sound in speech. This was the subject of an annotation in the *Journal* of Aug 14, p. 347. Dr A. E. MOURANT discussed the ethnological distribution of the Rh and MN groups. Whereas the ABO groups showed significant variations over distances of the order of 100 km, he pointed out, the MN and Rh groups appeared to vary more gradually, and the Rh system in particular promised to throw much light on racial relationships. In Asiatics, American Indians, and peoples of the Pacific, he stated, the CDe (R<sub>1</sub>) and cDe (R<sub>2</sub>) gene combinations predominate in varying proportions. Among negroes cDe (R<sub>0</sub>) is by far the commonest combination and shows that the negroes are quite different from all the so-called negroids of the East so far tested. In Europe CDe and cDe are common together with cde (r). 'Since the present Rh frequencies in Europe appear to be unstable over a long period, it is probable that their distribution is due to a mixing, at the end of the Palaeolithic period, of a stock akin to the modern Basques, who have nearly 30% of dd (mostly cde/cde) individuals with a predominantly Rh positive (or D) stock almost certainly from Asia. All the other characteristics of the Basques are in keeping with the theory that they are the almost pure representatives of a people which, mixing with other peoples from the East, gave rise to modern Europeans. Thus it is that the Basques are the most European of Europeans, while the people of the rest of Europe, Aryans and Jews, Nordics and Alpines, Celts and Slavs, are all half-breeds—'and who shall say that we are any the worse for it?'

Dr P. L. MOLLISON discussed the clinical significance of the Rh groups and gave a reminder that haemolytic disease of the newborn in man is paralleled by a similar condition in newborn mules. In this case the mule inherits from its sire, the donkey, an antigen which is foreign to the mare, and the mare forms antibodies which in turn cause destruction of the mule's erythrocytes.

## Ape and Human Evolution

Professor W. E. LE GROS CLARK discussed the bearing on human evolution of fossil remains of early Miocene apes collected from the Kavirondo Gulf area of Lake Victoria by the British-Kenya expedition directed in the field by Dr L. S. B. LEAKE. 'With the accumulation of so much new material,' he stated, 'it has become apparent that in early Miocene times East Africa was populated by anthropoid apes of many different types, show an astonishing diversity of form and size. Of particular interest are some of the limb bones discovered, for up to recently our knowledge of extinct apes has been practically confined to jaws and teeth. These limb bones consist of the shaft of a humerus, two fragments of clavicle, almost a complete femur and portions of others and some ankle bones (calcaneum and talus). They evidently belong to one of the large apes, probably *Proconsul* (first described by Hopwood) and are similar in general dimensions to those of a chimpanzee. But they show significant differences from the latter, particularly in the slender proportions of the shafts and long bones and in certain features in which they resemble those of cursorial monkeys rather than the modern brachiating apes. They appear to indicate that these early Miocene apes were lightly built creatures which had not become specialized for a completely arboreal existence but were capable of running and leaping with considerable agility, in strong contrast with modern anthropoid apes. These observations have an important bearing on the problem of human evolution, since many have argued that, in spite of their evident relationship, limbs of human type could hardly have been derived from those characteristic of the modern anthropoid apes. (The Miocene period is estimated to have lasted for possibly 20 million years and the Pliocene, which followed, for possibly 13 million years.)

**'ESTIGYN'****(Ethinyl Estradiol B.D.H.)***An Orally Active Derivative  
of the Natural Oestrogen, Oestradiol*

Ethinyl oestradiol is unique in that it is a simple derivative of the natural ovarian hormone which is highly active when administered orally. It is now available for clinical use as 'Estigyn'.

'Estigyn' may be prescribed in all cases in which an oral oestrogen is indicated, especially those in which the physician hesitates to prescribe one of the synthetic, non-steroid oestrogens.

Toxic reactions, such as headache, nausea and vomiting, are rare following the administration of 'Estigyn' and are most unlikely after the usual therapeutic doses. 'Estigyn' is termed in tablets containing 0.05 mg each tablet scored for convenience in giving doses of 0.025 mg when these are required. Literature is available on request.

THE BRITISH DRUG HOUSES LTD LONDON N1

**'AVLON'**

brand

**PENICILLIN  
LOZENGE B.P.**

Designed for slow dissolution when placed in the mouth, 'Avlon' Penicillin Lozenges provide a convenient, pleasant and effective means of maintaining bacteriostatic concentrations of Penicillin in the saliva. They are, thus, of value in the prophylaxis and treatment of infections of the mouth due to penicillin-susceptible organisms. The lozenges have proved highly effective in the treatment of post-operative dental infections and infective conditions of the oral mucous membranes, e.g. Vincent's angina.

**Dosage:**

The lozenges are given at intervals of 1 or 2 hours and should be allowed to dissolve slowly in the mouth without sucking or chewing, treatment being continued for several days according to the condition of the patient.

**Packing:**

'Avlon' Penicillin Lozenges each containing 500 units of penicillin calcium salt are issued in air-tight containers of 25.

# Progress in Therapy

A CONSTANT AIM of Boots' research department is to explore every possibility in drug production and place the results at the disposal of the medical profession. The following are three recent additions to the comprehensive range of Boots' Products for Modern Therapy.

## I Injection of Tetraethylammonium Bromide-Boots

For relief from pain in peripheral vascular disorders, causalgia, and post-herpetic neuralgia.

## 2 Nitrogen Mustard Hydrochloride-Boots

A powerful cytotoxic agent, for intravenous injection in cases of Hodgkin's disease, chronic myelogenous leukaemia and certain other malignant conditions.

## Penicillin (CALCIUM SALT) Oral Tablets-Boots

A convenient alternative to injection in some cases. Each tablet contains 50,000 units of CALCIUM PENICILLIN and 1G of sodium citrate.

Literature on these products is available on request from the Medical Department.

BOOTS PURE DRUG CO. LTD., NOTTINGHAM

## LIVER at meal times

## In a Palatable, Readily Acceptable Form.

Proteolysed Liver A & H is prepared by a process which eliminates the nauseating flavour of raw liver. Its palatability has been further improved by its presentation in a paste form. It may be readily incorporated in the normal diet by its inclusion in soups or on toast, bread or dry biscuits.

In pernicious anæmia and other megalocytic anæmias, proteolysed liver has proved effective in cases which have failed to respond to extracts of liver in general use.

In the same section Dr K P OAKLEY described the first successful use of the method of dating fossil bones by comparison of their fluorine content with that of other bones of known age and from the same district. The method is a revival of one proposed, although without explanation, by A Carnot, a French nineteenth century mineralogist. It depends on the fact that the hydroxy apatite (calcium phosphate) of bone gains in stability by conversion to fluor-apatite as fluorine is absorbed from ground water, and at last year's meeting Dr Oakley had described its attempted use on the skull of "Kanjera man" from the Kavirondo Gulf region. The only result in this case was to suggest that the water of the district must be abnormally high in fluorine content, since all the bones tested, irrespective of age, had developed the maximum proportion of fluorine which is chemically possible, and as a direct result the water supplies of this district have in fact been found to contain an undesirable amount of fluorine for human consumption. This year's comparison, which was carried out in the Government Chemist's Laboratory, was between specimens of bone of known origins from the Swanscombe region of the lower Thames valley and samples of the "Galley Hill skeleton," the antiquity of which has long been subject to discussion. Preliminary analyses show a difference of the order of 20 to 1 in fluorine content between upper Pleistocene and recent, and of 10 to 1 between middle Pleistocene and recent, with the samples of the Galley Hill skeleton coming nearer to recent. "In conjunction with other evidence," Dr Oakley stated, "they indicate that the Galley Hill skeleton was not contemporary with the 100-ft terrace deposits in which it was found, but a later burial."

### Section of Physiology

In the section of physiology Professor H HARTRIDGE devoted his presidential address to the case for a polychromatic mechanism of colour vision, which he thus summarized:

Until a few years ago it was possible to account for nearly all the aspects of human colour perception on the basis of the three-colour theory, but this is no longer the case. This is largely due to improvements in the older methods of investigation and to the invention of new ones. Among the latter may be mentioned the micro electrode technique of Granit, and the retinal direction effect of Stiles and Crawford. Modern requirements are met by a polychromatic theory comprising seven types of receptor, but there is no necessity for these to have such narrow spectral response curves as those exhibited by Granit's modulators. Modifications of the three colour and four colour theories have been examined to see to what extent they can be made to fit in with experimental results. Particular notice has been taken of the possibility that there is polychromatism of the retinal receptors but trichromatism of the nerve paths, which connect these to the brain, or even of the brain itself.

Sir HENRY DALE introduced a discussion on the transmission of effects from the endings of nerve fibres. He took as a starting point the hypothesis that chemical transmission from nerve endings to effector cells or secondary neurones was universal in all efferent fibres. On this basis a number of questions arise, some of which are being answered by current research. Given the existence of cholinergic fibres in which acetylcholine appears to be the sole transmitter, and of adrenergic fibres in which recent evidence suggests noradrenaline rather than adrenaline itself as the primary transmitter, does the finding of a high proportion of histamine in certain fibres (by von Euler) imply the existence of histaminergic fibres as well? Why should chemical transmitters be found along the whole length of fibres, with enzymes to build and destroy them, and not merely at nerve endings, when the evidence is against their concern with intraneural conduction? Why does one known transmitter inhibit and the other augment an involuntary effect or function? How can we combine the physiological evidence of Professor F R Miller and others suggesting transmission by acetylcholine at some central synapses with the biochemical evidence of Dr W Feldberg and Miss M Vogt at Cambridge limiting the suggestion to certain neurones only?

Professor F R MILLER then summarized the evidence for the stimulation by eserine and acetylcholine of "many varieties of synapses" the effects of both drugs being opposed by atropine. Dr Feldberg's approach has been through the extraction with saline of the enzyme system responsible for the formation *in situ* of acetylcholine. Like Sir Henry Dale, he made the point that synthesis was a property of the whole neurone and not

only of the nerve ending, and he stated that only a few milligrams of tissue were enough for investigation—e.g., in small but well-defined areas of the brain and medulla. Acetylcholine was not the universal synaptic transmitter in the central nervous system, and often, but not always, neurones with high and low acetylcholine content appeared to alternate in both afferent and efferent nerve pathways. The alternation of mechanisms thus suggested he found attractive to the extent that some caution was necessary in interpreting the evidence.

### Problems of Old Age

A discussion under this title attracted wide attention, due principally to the challenging statement by Sir ERNEST ROCK CARLING that the old should "revolt" against what he described as "the 60 to 65 convention." "Complacent acceptance of the hitherto economically convenient belief that chronological age is inevitably associated with incapacity," he stated, "is a potent influence in determining its validity. It should be combated resolutely in the interests of individual health and happiness as well as national advantage. There is as much reason to assert that the range should be 65-70 or even higher." Dr MARJORY L WARREN followed with an outline of the organization and research needed for the "medical care and welfare of the elderly sick and infirm," but included among her suggested remedies "plans for keeping elderly persons usefully employed whenever possible." Other points which she made included the need for social as well as medical care to assist elderly people to remain at home in comfort and happiness, the desirability of establishing geriatric units based on general hospitals, and the need for the closest liaison between regional hospital boards and local authorities.

### Colour Vision in Animals

A discussion on colour vision in animals was held by the section of zoology. This brought a compact statement by Dr R J PUMPHREY on the evidence of experiment, while Dr G S CARTER summarized the evidence of behaviour. Dr Pumphrey pointed out that training techniques could be applied only to animals which were "active, purposeful, rational, and docile," although in some few cases it was possible to provide experimental evidence of other kinds—e.g., that fishes which could change their colour to match their background would then choose a background to match their colour. "Colour perception," he summed up, "has been demonstrated beyond reasonable doubt among invertebrates in some insects, among vertebrates other than animals in some bony fishes, reptiles, and birds, and among mammals only in some monkeys and apes and man. There is a significant difference between insect and vertebrate colour vision. The former seem to see colour as long as they can see at all whereas vertebrate vision becomes achromatic at low intensities. All nocturnal vertebrates are probably colour-blind, and the ancestors of the mammals as a group are believed to have been nocturnal." Dr Carter pointed out that the perception of pattern as well as colour was necessary for the effective use of colour vision. Animals reacting to the detail of other animals he listed as, in the sea, fishes and cephalopods, on land, some insects, a few spiders, and those vertebrates that have colour vision.

### Physical Science

In the physical sciences the most important single contribution was probably an account by Dr GEORG THIESSEN, of Hamburg Observatory, of some new and difficult observations on the general magnetic field of the sun. The effect was to weaken seriously the theory of "cosmic magnetism" advanced by Professor P M S Blackett rather more than a year ago and to suggest, if only tentatively as yet, that the sun's general magnetism may vary in a cyclical manner. Whereas in 1945 Dr Thiesen had obtained comparatively high figures, used by Professor Blackett in his theory, in 1947 and 1948 he had failed to find any measurable effect although one-tenth of the 1945 figure should have been detectable. More observations were used in the two later years than in 1945, and to confirm the reality of the apparent variation it would be necessary to extend the work so as to include different phases of the sun-spot cycle. Professor Blackett's theory was, in brief, that any massive and rotating body is automatically a magnet and that

its magnetic properties could be calculated quantitatively from (approximately) its mass, radius, and speed of rotation

In the same section Mr D A OLIVER described the development of a new permanent magnet alloy, still at the experimental stage containing a small proportion of the rare element niobium, which has also lately been used in special alloys for jet engines. Dr D GABOR described a new principle of microscope design by which it is hoped that the resolution of the electron microscope can be further increased without the necessity for "fully corrected" electron lenses such as those used in optical microscopy

## SPEECH THERAPY CONFERENCE IN LONDON

London has been the centre for a number of international conferences this summer. Following the Mental Health Congress and the Congress of Industrial Medicine, two smaller conferences of an international character were held at the end of September, one of them a conference on speech therapy, which was attended by delegates from the Dominions, the United States, and six European and two South American countries and the other the annual congress of the Chartered Society of Physiotherapy, an account of which is held over until next week.

The conference, under the auspices of the College of Speech Therapists, was held in the hall of the Royal Society of Medicine. Mr DAVID H PYE, FRS, provost of University College London, who presided over the opening session, mentioned that it was exactly twenty-five years since the establishment in the Phonetics Department of University College of a centre for the correction of speech defects. Speech difficulties, said Mr Pye, were as old as history, methods of alleviating them were practised by the early Greeks, and treatment was occasionally attempted in the Middle Ages and after the Renaissance though the methods were largely empirical and did not appear to have been very successful. Only within the last thirty years had it been possible to see the problem in its scientific perspective.

### Scope and Aims of Speech Therapy

The first of some thirty papers surveying the whole field of speech disorders was by Miss JOYCE WILKINS, lecturer in spoken language at University College Nottingham. She pointed out that the reason why it was not until the twentieth century that the importance of speech therapy was recognized was because the spoken word was then beginning to challenge the dominance of the printed or written word. Printing had for many generations dominated education, and the spoken word, which was transitory, was deemed of small importance. Now, with the transmission of sound regardless of barriers of time and space the wheel had turned, and the importance of speech for good or ill was manifest. Advances in medicine and surgery—especially in neurology and in plastic surgery—had assisted the development of speech therapy.

The number of registered speech therapists in this country was 340. There were six training centres—four in London and two in Scotland—and the course of training took three years. School speech clinics numbered 230. More school clinics were needed and also facilities for the continued treatment of young people after leaving school. The National Health Service Act did not specify speech therapy among the services to be provided, and its position under that Act had still to be defined but it was expected that provision would be made for speech therapy centres under the Regional Hospital Boards. The regulations made under the Education Act 1944 laid it down that education should be provided for certain classes of children including those with speech defects. It was estimated that from 15 to 3% of the children attending school needed some treatment for speech disorders and in addition many young people attending colleges and universities needed attention. It would be desirable to have general speech training for children who were handicapped by deafness. There

were not enough speech therapists in the country for this purpose, speech therapists should be attached to all schools for the deaf and lip reading should be included in the training of the speech therapist.

### The Child Stammerer

A long discussion took place on stammering. The emotional background was reviewed in papers by Dr LEOPOLD STEIN of the Tavistock Clinic, and Mr NORMAN BRANGHAM. Dr STEIN said that in infancy speech and thought were one entity but at about the age of 4 there was a splitting apart of thought and feeling on the one hand and utterance on the other. It was not always easy to bridge this gap, especially when it was of more than average width, and disharmony might arise. The speaker was still able to send out his messages, but under stress, so that a stammer resulted. In the conflict resulting from inability to form words the speaker would make a headlong flight towards safety. In reply to a school medical officer who suggested that stammering was not necessarily connected with anxiety, because in his experience a large number of child stammerers were not at all of the shy or nervous type, Dr Stein agreed that the stammering was not to be defined as an anxiety state, it went psychologically deeper, but anxiety might supervene.

Mr BRANGHAM said that in its origin stammering was not different from neuroses in general, it was found in a well-differentiated group of personality structures. It represented a specialized form of neurotic conflict, indeed, it represented not only a conflict but an attempt to resolve it. The stammerer had gone a stage further in the resolution of his conflict than the person with neurotic disorder, for while the latter was trying to work out his difficulties internally the stammerer had partially solved his difficulties on the physical level so that it was probable that sexual disturbances were found less frequently among stammerers than among neurotic personalities in general. The neurotic component in the stammerer had been almost completely abolished.

The experience of one speech therapist related in the discussion may be quoted. She had been treating a small boy, who at last said, 'I will never stammer again. I will blink instead.'

### Dysphasia and Recurrent Speech

Dr MACDONALD CRITCHLEY addressed the conference on speech disorders, particularly the phenomenon of recurrent utterance. The aphasic person, he said might be left with a single word or phrase, sometimes 'Yes' or 'No' or a meaningless snippet of jargon. The master of French poetry, Baudelaire, when stricken with aphasia could utter only three words. When a patient's speech had been restricted for some time to one phrase he might be able to vary the intonation so as to express greeting or affirmation or negation and so on. Hughlings Jackson suggested that the recurrent phrase was the one which the patient was about to utter at the moment of his stroke, but Gowers—in many ways a more accurate observer—believed that it was the phrase he had just spoken. One of Dr Critchley's patients, wounded on D day, could say only 'Yes it's to day'—very likely his last remark to a comrade who had asked the question. Sometimes such patients with restricted speech would utter something else quite unexpectedly and incongruously. One patient at Queen Square whose speech had been limited for a long period to 'Yes' and 'No,' at a moment when his case was being discussed with a group of students piped up the astonishing word 'unilaterality'.

Another phenomenon was a repetition of the last word or two of a sentence, or a frequent repetition of the same phrase. Dr Macdonald Critchley quoted a passage from a speech by one of the most famous men in England to illustrate what was really whether consciously or unconsciously a trick of oratory. Another "normal" verbal mannerism was the use of some silly phrase, almost devoid of meaning to prefix sentences such as 'Don't you know,' 'As a matter of fact, or worst of all. Actually.' Some persons were addicted to a verbal tic whereby in the middle of ordinary sentences they uttered an incongruous word or phrase often an expletive. The

enunciation of the same phrase over and over again in psychosis was a phenomenon belonging to the realm of the illness rather than to that of the dysphasia. There were also persons whose tic or mannerism led them to repeat every question asked them, sometimes with a change of tense or pronoun and sometimes not.

Some remarkable examples of repetition in writing were given by Dr Critchley. One was a verse by one of the most distinguished of French poets which consisted of the single word *persienne* repeated twenty times. The title of the poem was inevitably *Persienne*. The patient's previous personality, educational status, and in particular his literary and verbal ability were important. Thus an illiterate person of limited vocabulary was not likely to suffer so much from a slight vascular lesion as an orator or writer. A judge who was accustomed to sum up on the bench extemporaneously, choosing his words with precision, knowing that they might be closely examined in a court of appeal, was probably using speech in the mostly highly evolved way in which it could be employed, and thus he had a very vulnerable speech mechanism, and a small lesion would cause disproportionate suffering and disability.

On the question whether women were more aphasic than men, Dr Critchley said that women ordinarily were more fluent but men took more interest in speech for its own sake, deliberated over *le mot juste* were inclined to use the *double entendie* the wisecrack, and the pun, and therefore perhaps men had a more vulnerable speech mechanism than women, and the same injury might produce in men a more crippling degree of aphasia.

Dr W. RUSSELL BRAIN said that Hughlings Jackson pointed out many years ago that patients who could say nothing else could still swear, and swear, so to speak, appropriately. It seemed to him that the organization in the nervous system for swearing must be different from that for ordinary speech. Men of a certain type whose speech was peppered with lurid adjectives which were apparently used almost unconsciously, were able nevertheless, when a lady entered the room, to continue their speech without any of these "adornments" rather suggesting a difference in the neural mechanism whereby obscene could be switched on and off. Not all compulsive utterance, of course, was in the nature of swearing. Did not Dr Johnson withdraw behind a curtain to utter prayers? Dr Brain had a patient who after a stroke could say nothing but "No," but he was able to sing, his repertoire consisting of one music hall song. The ability to sing was worth bearing in mind for the purpose of treatment.

In the four days of the Congress on Speech Therapy papers were presented by members of the College on such subjects as the symptoms and treatment of dysphasia due to head injury, the associated conditions of dysgraphia and dyslexia, the oesophageal voice following total laryngectomy, relaxation therapy and the nervous patient, the school clinic and the speech-defective child, and the psychological approach to the pre-school stutterer. The Californian programme of speech correction in the schools was described by a visitor from that State, a cinematographic instruction demonstration of the visual hearing method of teaching the hearing-handicapped was given from the clinic in Ohio State University, and a Uruguayan visitor described the progress of speech therapy in South America. The work of special schools in Holland, Czechoslovakia, and Denmark was also described, and a French visitor gave an account of the relation of dental medicine to speech therapy. The role of emotional problems in producing disorders of speech was the subject of a paper by Dr E. M. CREAK of the Great Ormond Street Hospital.

The speech therapists are numerically the smallest of the medical auxiliaries but the conference fully demonstrated their enthusiasm and pride in their service.

In 1946 the Ministry of Health began intensive training courses in nursing for ex-Service men and women with nursing experience. Out of 179 of these men and women who took the recent final State Examination 163 were successful. The proportion of passes (91%) is well above the average for normal student nurse training schools. Up to the present date 620 of these ex-Service students have qualified as State Registered Nurses.

## Correspondence

### Diabetic Coma

SIR—The paper by Professor R. H. Micks on diabetic coma and his reference to my colleague Dr. Howard F. Root's plan of treatment in the *British Medical Journal* of July 24 (p. 200) and the comments upon it by Drs. Lawrence and Oakley (Aug. 7, p. 310) lead me to send you the summary of treatment we are distributing to doctors taking our courses or at medical meetings.

#### Treatment of Diabetic Coma

##### FIRST HOUR AFTER ADMISSION

Assign a special nurse, experienced in coma treatment, for the first few hours.

##### LABORATORY

- 1 *Urine* Examine for sugar, diacetic acid, albumin, coma casts and pyuria. Catheterize if necessary.
- 2 *Blood* Test for sugar and CO<sub>2</sub> content, with emergency report inside the hour. White blood count and non-protein nitrogen also of value.
- 3 *Search for Complications* A History to explain cause of coma. B Physical examination, noting particularly—(a) State of consciousness, type of respiration, pulse rate, blood pressure, and rectal temperature. (b) Look for soft eyeballs, dry tongue, dilated stomach, cold and mottled skin, and impacted rectum.
- 4 *Insulin* 100 units of crystalline insulin subcutaneously at once for adults, if blood sugar exceeds 300 mg per 100 c.c. and if the blood CO<sub>2</sub> content is 9 millimols per liter (20 volumes per cent) or less. The dose would be proportionately less in cases of recent onset of diabetes or in young children. In cases with blood sugar between 600 and 1000 mg give 200 units additional, and with blood sugar over 1000 mg give 300 units additional. In patients in circulatory collapse, give preliminary additional doses of insulin intravenously.
- 5 *Gastric Lavage* Use large tube, aspirate completely and wash stomach with warm water with greatest care.
- 6 Normal saline intravenously, 2000 c.c. and repeat if indicated by dehydration and blood pressure below 90 mm Hg. Avoid too rapid administration, especially in older patients.
- 7 Keep patient warm yet avoid burns, as from hot water bottle.

##### SECOND TO SIXTH HOUR

Occasionally the gravity of the case necessitates repetition of first hour's total insulin in the second hour.

8 Repeat blood sugar and CO<sub>2</sub> determinations after three hours. For rising blood sugar give insulin 50-200 units, according to physician's judgment of prognosis.

9 *Fluids by mouth* (as soon as tolerated), 100-120 c.c. per hour of broth, ginger ale, orange juice, tea or coffee, to be sipped by patient or spooned by nurse. If nausea and vomiting recur, withhold fluids orally for 12 hours (lavage stomach again if indicated) and then resume.

10 Soft or liquid food such as oatmeal gruel, orange juice or milk diluted half and half with lime water, not to exceed 10 gm carbohydrate per hour.

11 *Enema* for cleansing and to relieve abdominal distension.

12 Record blood pressure, pulse and temperature. Note signs of improvement, or the reverse.

13 Urinalysis for sugar and diacetic acid every hour. Record volumes.

##### SIXTH TO TWENTY-FOURTH HOUR

14 Repeat blood sugar and CO<sub>2</sub> determinations and give insulin 50-200 units if blood sugar and CO<sub>2</sub> levels are not improving.

Insulin (crystalline) may now be given according to urine tests every 1 to 4 hours if fall in blood sugar has been satisfactory.

If test is—

Red	Orange	Yellow	Green	Blue
Give— 20	16	12	0	0

units

15 *Urinary output* Observe this closely and note with alarm any sign of anuria. Treat with 1500 c.c. intravenous saline if shock is persisting. Repeat as necessary. For anuria, associated with hypochloremia, give 50 c.c. of 10 per cent salt solution intravenously. Never give hypertonic glucose solution to promote diuresis. Beware producing excessive diuresis with consequent loss of base, especially of potassium.

##### SECOND DAY

16 *Soft Food*—Diet carbohydrate 100 to 150 gm, protein 50 gm, fat 50 gm.

17 Protamine zinc insulin should be begun, supplemented by crystalline insulin in small to moderate doses before meals, as indicated by blood sugar and urine tests

### THIRD DAY

18 Patient should gradually return to the standard diabetic diet for age and weight with carbohydrate 150 to 200 gms, protein 60 to 100 gms and fat 60 to 120 gms daily

Possibly this summary may be of interest because it provides against excess of treatment or the reverse. Constructive criticisms of this summary will be welcomed. We recently had 92 cases of diabetic coma in succession without a death—I am etc,

Boston

ELLIOTT P JOSLIN

### Clinical Research

SIR—The reading of the recent excellent series of articles in the *Journal* on medical research and of Dr Walshe's letter (Sept 18 p 572) has stimulated me to some observations on clinical research, which term seems in need of definition.

Clinical medicine is the investigation and treatment of people who are ill with the object of making them well. Clinical research is the endeavour to advance knowledge while practising clinical medicine. In an ideal world clinical medicine would be reduced to small dimensions through preventive medicine, but it is obvious, with such a large proportion of disease at present unpreventable, that the main endeavour of medical research must until this situation changes be at the disease level.

Various fallacies exist about clinical research. An extreme example, now fortunately rare, is the denial that it exists at all, usually coupled with the assertion that the sole task of the clinician is to exploit the discoveries of the laboratory. Clinicians from all fields of medicine would find it easy to draw up lists, comparable with that given by Dr Walshe for neurology, which would disprove this fallacy and its endeavour to reduce clinicians to the level of medical helots. A less extreme but more subtle example of the same fallacy is often provided when clinicians retire from the ward to the laboratory for their research. Almost all will agree that a training in laboratory research is an invaluable preparation for clinical research, that most forms of clinical research need, or benefit by, the added precision and definition of laboratory investigations, and that many clinical problems can with profit be transferred to the laboratory. But a clinician who transfers both himself and the problem to the laboratory is not carrying out clinical research but laboratory research.

Another fallacy is to regard physiological research on patients as clinical research, whereas it is really the using of a conveniently situated group of individuals for physiological studies, just as in the same way medical students or nurses are often used. Modern clinical medicine (and perhaps surgery in particular) is a highly developed branch of experimental biology and affords full opportunities for the exploitation of the most fruitful scientific techniques—the experimental method and the accumulation of verifiable quantitative data. But the research worker fresh from the laboratory may find himself in difficulties in the application of these techniques to clinical medicine. The experimental method has often to be modified to fit therapeutic necessities. It is rare for it to be feasible to treat alternate cases and even when it is, mankind and his diseases are so individualistic that the two groups so formed may not be fully comparable, and the clinical research worker must often seek truth in small numbers.

Research requires careful planning and staff work, a sound plan being equivalent to the initiative of military parlance. But, if one may continue the military metaphor, over such a large area of medicine is the initiative still with the enemy that the intelligence branch of staff work still has enormous importance, with its endeavour to build up a reliable picture of the enemy's design from scraps of incomplete information. And purely observational methods particularly with the constantly advancing modern methods of observation, still have a big part to play in clinical research.

In conclusion may I be allowed to congratulate the *British Medical Journal* that in its educational number medical research has been given such an important place—I am etc

DAVID H PATEY

### Stainless Steel Wire

SIR,—The report entitled "Stainless Steel Wire for Closing Abdominal Incisions and for Repair of Herniae" by Messrs A Lawrence Abel and Alan H Hunt (Aug 21, p 379) is I believe, an important contribution to abdominal surgery. These authors have had no instance of abdominal disruption or post-operative herniation in more than 2,500 major operations, many of which were in debilitated patients with gastro-intestinal tract malignancy. Wire was first used as a suture material by J Marion Sims in the closure of vesico-vaginal fistulae, and was first advocated for use in abdominal incisions in 1934 by Babcock, Jones, Newell, and Brubaker of the Cleveland Clinic, Dambin, and Kaufmann, Johnson, and Yesser have all reported excellent results with the use of wire as a suture material, yet the majority of surgeons continue to use catgut, silk and cotton.

My impressions of stainless steel wire for the closure of abdominal wounds may be of interest because I use it exclusively in this regard. I first saw wire used by the late Hugh Hampton Young when I was house officer on his service at the Johns Hopkins Hospital. He employed it in the repair of hypospadias, extrophy of the bladder, and in operations for pseudo-hermaphroditism with results that are world renowned. Later, as resident in surgery at the University of Michigan Hospital, Ann Arbor, I had the opportunity to observe many patients in whom wire was used for abdominal closure. This suture along with transverse abdominal incisions has been advocated for some time by Coller. Coller has extended the use of wire to include closure of the subcutaneous tissue and skin (each by means of a continuous heavy wire which is pulled out at the end of eight days or so). In the case of the skin this wire is subcuticular. Recently he has used continuous wire also (which is not removed) to close the peritoneum. In the transverse incision interrupted wire stitches are used in the anterior and posterior rectus fasciae and other fasciae. No suture is used in the rectus muscle itself.

Since July 1, 1947, I have used stainless steel wire in all major abdominal incisions made on my service at the Alexander Blain Hospital and Clinic, Detroit. Transverse incisions have been used in all abdominal cases with the exception of three patients with "acute abdomens" in whom the pre-operative diagnosis was too obscure to know where to place a transverse incision. In a few other patients it was necessary to add a vertical limb to an incision which was transverse. In the treatment of herniae the McVay technique (sewing the conjoined tendon to Sir Astley Cooper's ligament) has been used in all inguinal and femoral ruptures except the small indirect inguinal type where excision of the sac alone seems sufficient. Wire has been used throughout.

Incisions closed with wire have been found to be no more difficult to reopen than incisions closed with other materials. This is true even when the peritoneum has been closed with a continuous steel wire stitch. I consider the transverse wounds closed with wire and with subcuticular wire in the skin far less prone to infection or disruption than ordinary vertical incisions closed with catgut and silk. Certainly early ambulation can be employed with far greater confidence when the former type of closure has been made. Cosmetically, the transverse incisions closed with wire give the most superior results. I have seen I agree with Abel and Hunt that vitallium wire is too brittle and expensive to use and that stainless steel wire from all theoretical and practical standpoints is the suture material of choice.

It would be of interest for Abel and Hunt to extend their use of wire to the closure of the peritoneum and of the skin. A subsequent report by them on these aspects of its use would make another valuable contribution to surgical literature—I am etc

### Prevention of Dental Caries

SIR—Dr H H Neumann's opinion, quoted by Sir Leonard Hill (Sept 18, p 573), is not consistent with the evidence. No such condition as 'disuse odontoporosis' has ever been demonstrated, and there is no evidence whatever that the population is suffering from it. Teeth which fail to erupt and are

therefore completely disused have not been shown to differ in composition and structure from those which have erupted normally and have been used. Even in severe hyperparathyroidism no odontoporosis occurs. While it is known that the vigorous chewing of tough and gritty foods is generally associated with freedom from dental caries, the relationship between the two is not simplified by inventing such a concept when more credible explanations exist.

Structural defects due to nutritional, among other, causes are at least known to occur, though Lady Mellanby's assessment of them in the mouth must suffer unfortunately from the subjective nature of her test. However, the most striking and least controversial finding in the paper by Lady Mellanby and Dr Helen Mellanby (Aug 28, p 409) is the accelerated improvement in caries experience in the 5-year-old school-children in 1945-7 compared with 1943-5. Unless the other influences beneficial to the teeth exerted by war conditions can be shown to have had reason to operate more powerfully in the latter period, there will be little cause to reject the view that an important part of the improvement between 1945 and 1947 was due to the fact that throughout their whole lives the children in the last group had better access to, and made more use of, a number of valuable nutrients. The opinion that these may have acted through an improvement of tooth structure is in the present state of our knowledge a reasonable one.

This does not mean that encouragement of the use of foods containing sufficient fibre to require vigorous mastication would not produce further benefit—though hardly by elimination of odontoporosis.—I am, etc.,

London SE 1

M A RUSHTON

### Cervical Sympathetic Paralysis

SIR—As Dr J Donaldson Craig and Mr R C Fuller point out in their paper (June 19 p 1182) on this subject, the scholarly review of Ogle (1858) should entitle him to the credit that is given to Horner, but the British, with characteristic modesty have allowed the honour to pass elsewhere. The first description of the syndrome in man was by Edward Selleck Hare (1838) who died from typhus at the age of 26 on the day before his article appeared. The sad story has been told by Fulton (1929). John Reid (1839), of Edinburgh, is another British contributor to clinical and experimental knowledge of the syndrome. Early in this field (as in many others) was Sir James Paget (1864) whose celebrated case of causalgia with 'glossy fingers'—due to a traction lesion of the brachial plexus—presented a contracted pupil on the same side.—I am, etc.,

### Acute Porphyrin

SIR—The cases of Dr Ernest Petrie (May 15, p 926) and Dr M G Good (Sept 11, p 531) illustrate the difficulty of diagnosing acute porphyria even when the diagnosis is suspected. During the last six years I have been able to study not only the patient reported with D Silva in this *Journal*<sup>1</sup> but also a case of acute mania due to lead poisoning which showed intense coproporphyrinuria. This comparison and the consequent review of the literature led me to review the problems of differential diagnosis, and a summary of my conclusions may be of interest.

Every major symptom and sign of lead poisoning may occur in acute porphyria—loss of weight, hypertension, colic, encephalopathy (including coma), confusion, acute mania, and peripheral neuritis—though the nervous manifestations are usually more extreme in porphyria and may simulate an ascending myelitis. Porphyrin, therefore must be suspected in any obscure case which simulates lead poisoning. With porphyria in mind the diagnosis can be confirmed only by meticulous examination of the urine using the hand spectroscope.

In porphyria the characteristic and diagnostic pigment is uroporphyrin but small quantities of coproporphyrin are always present with variable amounts of urobilin and indirubin. All these pigments may be excreted preformed but more often they are present

as colourless chromogens which must be converted to the pigment before identification is possible. The concentration of the various pigments and their chromogens fluctuates widely and independently from day to day. Indirubin, soluble in toluene, contributes most to the "port-wine colour" of the urine, while the porphyrins themselves affect the colour comparatively little, so that the same patient may on one occasion pass urine which after standing an hour or two resembles tawny port but contains a mere trace of porphyrin, and a week later urine which is only a little more brown than usual but contains relatively large amounts of porphyrin. Two cases in which the clinical manifestations were typical and the urine dark but free from porphyrin, and a third in which porphyrin could be detected only during remissions, have been reported, so that repeated examination of the urine may be necessary.

In examining the urine the essential points are the differentiation between urobilinogen and porphobilinogen, the chromogen of porphyrin, and that between uroporphyrin, characteristic of porphyria, and coproporphyrin, which occurs also in a variety of diseases including lead poisoning, hepatic cirrhosis, pellagra, and pernicious anaemia. The former is accomplished by the Watson and Schwartz test, the latter by attempting to extract the porphyrin with ether, coproporphyrin alone can be extracted with this solvent, and in porphyria it is usually present only in low concentration.

My standard procedure is therefore (1) Place 500 ml of urine with 20 ml of toluene in a litre bottle and stand it in front of a window for several days, mixing occasionally. If indirubin or its chromogen are present, the urine will darken and some of the pigment will pass into the toluene layer, colouring it pink. Indirubin occurs in the urine of patients with porphyria, pellagra, and many deficiency diseases, but rarely reaches a high concentration save in the first two.

(2) To 10 volumes of urine add 1 volume of concentrated hydrochloric acid and stand overnight to convert chromogens to pigments. Add sufficient sodium acetate to render the mixture just alkaline to congo red paper, then as much again. Shake one portion five to ten times with ether, unite the ethereal extracts, and extract them with a small volume of 25% hydrochloric acid. Coproporphyrin enters the acid layer and if present in quantity colours it pink, so that the characteristic absorption bands can be seen with the spectroscope. Shake a second portion with a tenth of its volume of amyl alcohol and break the resulting emulsion by centrifuging. Transfer the amyl layer to a clean tube and add 1-5 drops of concentrated hydrochloric acid. Mix, and examine with the hand spectroscope. This extract contains both uro- and coproporphyrin.

(3) Perform the Watson and Schwartz test<sup>2</sup> to 1 ml of fresh urine add 1 ml of Ehrlich reagent containing 2.8 g dimethylamino-benzaldehyde per litre, and after standing a few minutes add 2-3 ml of saturated sodium acetate. Shake with 5 ml of chloroform. The pink colour due to urobilin is quantitatively extracted by the chloroform that due to porphobilinogen remains in the aqueous layer.

(4) Stain a blood film with Leishman's stain, diluting with water buffered to pH 7.2-7.4, and examine for punctate basophilia to exclude lead poisoning.

If these tests are applied by someone skilled with the hand spectroscope there will rarely be any doubt of the diagnosis, but I must emphasize the importance of repeated examination and of referring suspicious or doubtful urines to someone experienced in this field.

Between 1942 and 1947 I served directly hospitals containing over 1,200 beds and was closely connected with others with over 1,000 beds, yet only the one case of porphyria was recognized, in spite of careful search and repeated discussions with my colleagues. I believe a few English cases have been recognized but not reported, but I conclude that the condition is probably much less common in England than in Scandinavia, the population of which is less than twice that of Greater London. Dr Torben K. With informs me that Waldenström now thinks that the majority of Swedish cases are descended from one man who migrated to Sweden about 200 years ago.

During the last 200 years migration from Scandinavia to England has been slight, that to the United States considerable. If the genetic background needed for the manifestation of the disease were more common in Scandinavia than in England this might explain the comparative rarity in this country, while the studies of Darlington<sup>3</sup> on the genetic component of language, and those of Fisher and Taylor<sup>4</sup> and Hart<sup>5</sup> suggest that the disease might be more common in Northern Ireland and in Scotland.—I am, etc.,

## Maxillary and Mandibular Neuralgia

SIR—In the 71st *Interim Supplement* to the *British Encyclopaedia of Medical Practice* (August 1948), in an article on trigeminal neuralgia Dr Wilfred Harris has stated chronic maxillary and mandibular neuralgia. This is sometimes bilateral and may be a manifestation of neuropsychosis. Suggestion treatment or even electrical convulsion therapy is indicated. Such a statement, made by an authority of Dr Harris's reputation, would be widely accepted if allowed to stand uncorrected.

In the differential diagnosis of trigeminal neuralgia Dr Harris has made no mention of Costen's temporo-mandibular syndrome, although it is referred to by name on the previous page of the *Supplement*. Many cases of chronic maxillary and mandibular neuralgia are cases of Costen's syndrome which is due to closure of the bite—that is approximation of the mandible to the maxilla—in edentulous patients. Closure of the bite results from absence of teeth, badly constructed dentures, atrophy of the alveoli, or alveolectomy. It leads to narrowing of the temporo-mandibular joint. The strains placed upon the abnormal joint cause pain which may be unilateral or bilateral and which may be local or referred to the upper or lower jaws, eye, ear, or mastoid. Radiographic examination reveals narrowing of the joint space. The pain is relieved by fitting dentures or by building up the dentures to open up the bite. A similar syndrome may be reproduced by dentures which open up the bite too much.

These people should not be labelled as suffering from neuropsychosis. Suggestion treatment will do them no good, and electrical convulsion therapy may well do them harm—I am, etc,

Mr Hawthorn Western Australia

JAMES H YOUNG

## Use and Abuse of Tonsillectomy

SIR,—Referring to recent correspondence in respect of tonsillectomy, I would like to point out that in England and Wales in 1931 the proportion of children dealt with by operation was 2.2% of average attendance in elementary schools. This figure varied in different areas from 1% to 8.5%. Comments with regard to the frequency of operation reduced the rate to 1.49% of average attendance in 1934. The figure rose to 1.97% in 1938, fell to 1.12% in 1940, and then rose again. Of recent years in this area fewer children have been submitted to operation. In my opinion enlargement *per se* is not a good ground for operation. We judge each case on its merits and satisfy ourselves that operation is in fact needed before referring cases to hospital. Despite controversy on the subject I am of the opinion that the tonsils act as barriers against bacterial infections. They may have other functions. In cases of infection and mechanical obstruction a strong case exists for tonsillectomy but no rule-of-thumb method of assessment will give complete satisfaction—I am, etc,

Halfpenny

G C F ROE  
Medical Officer of Health

SIR—Your annotation (Sept 18, p 564) on the removal of children's tonsils is I venture to say, an admirable summary of the position *qua* tonsils, but with great respect may I ask if the picture is complete unless we include the question of adenoids? All that you have said in defence of tonsils will carry weight with everyone, but that great master of children's diseases Sir Frederic Still used to say, "Tonsils may be left but adenoids—never!" I can think of one case in which a parent firmly resisted the pleadings of an ENT surgeon to be allowed to remove the tonsils when taking out the adenoids of a little girl. The patient now a grown woman has had the minimum of infections and practically never a sore throat. Any revision of our views on tonsillectomy need not lessen our readiness to remove adenoids—I am, etc

Southsea, Hants

M ASTON KEY

SIR—Your correspondence columns have recently contained many unpractical and theoretical suggestions about tonsillectomy in children with which we do not agree. But your annotation (Sept 18 p 564) sums up the position and follows with the most impracticable suggestions of all. The writer appears to us to have no knowledge of the present conditions in the hospitals in London. We agree that tonsillectomy is a major

operation and never urgent. But surely the six months period of observation after the patient is referred to the surgeon is totally unnecessary and undesirable. The practitioner has always spent some time considering the patient before referring him to the surgeon, and an unnecessary six-months wait is an intolerable burden for the child with a nasal obstruction caused by adenoids.

At present, with operating going on all through the year, a child at an average London hospital will have an appreciable wait before he sees the surgeon. He will then be put on the waiting list and wait anything from six to eighteen months for operation. If the operation is now not to be performed in winter or early spring and postponed when any infectious disease is prevalent the waiting time will increase by anything up to five years. Clearly in the ideal future a vast increase in the number of children's beds allotted to the ear, nose and throat department at appropriate seasons will have to be made. In the meantime the only practical method of dealing with the problem is to keep all the beds allotted for children's tonsillectomy full all the year round. A definite statement made on the authority of the Editor of the *British Medical Journal* that children's tonsillectomy should not be done in the winter does not help in any way those who have to cope with this problem and only gives them a lot of trouble explaining to parents the necessity of operation in the winter if their child and others are ever to have the operation performed.

We agree with Dr A M Tait (Sept 11, p 534) when he states, "Clinically I doubt if there is any more satisfactory operation in childhood than the removal of septic tonsils and adenoids." This of course implies satisfactory selection of cases, and one sees so many entirely satisfactory results of operation that the statistics showing no benefit from the operation do not represent the results of operation in cases that we see and do not unduly influence the advice we give to parents.—We are etc

## Vaccination

SIR—In common with many others no doubt, I received a Ministry of Health brochure on how to vaccinate. A lot of it was interesting but there were some parts that cannot be allowed to pass without adverse comment. In the list of names at the end to whom the compiler is indebted there was none of any woman. It asserts that the arm should be chosen as the site of election on aesthetic grounds. I think that rather more than half the populace would disagree with this. It then goes on to state that general reactions are more common from vaccinations on the leg. I would disagree. In any event they are so rare as to enable one to disregard them completely.

One last point—it is also stated that infant vaccination can be performed at clinics and health centres as safely as at home. Of the vaccination this is true, but no infant should be exposed to the great variety of infections which it is bound to meet at such an agglomeration of children—I am etc

Strettle, Yorks

W A FISLIP

SIR—In Army and in civil practice both at home and abroad I have so often seen practitioners in difficulties in the vaccination of patients that I would like to draw attention to a simple solution. The rules for vaccination laid down in the Army manuals are clear enough. The skin should be purified with soap and spirit, then permitted to dry. A vertical linear scarification no more than a quarter-inch in length is made with a sterile needle above the insertion of the deltoid muscle, and any scarification which oozes blood discarded. After the lymph has been applied to the scratch an aseptic dressing should be applied, but only when the lymph has dried. So far so good. But how does the lymph get there? I have seen it blown on, wiped on, scratched on, and even applied with the blade of a penknife normally used for pipe cleaning. The last named gentleman, however, was old enough to cast scorn on the 'germ theory'. In spite of the nicotine his vaccinations seemed very successful.

It has always been my practice to use a bacteriological loop first sterilized in a flame. There is no contamination of the lymph: the dose is constant, and drying of the lymph is almost instantaneous. The resultant pustules showed practically no variation in size. In a series of 850 recruits, a little more than

half of whom bore the marks of previous vaccination, 55% of the vaccinated developed a good pustule at the first attempt and 98% of the unvaccinated. No secondary infection of the pustules was seen except in a case where a misguided house-surgeon, who cannot have attended his vaccination class, treated a normal pustule by two hourly fomentations—I am, etc

### Resuscitation by Rocking

SIR—I was very interested in the article by Dr F C Eve and the late Dr N C Forsyth (Sept 18, p 554) on rocking technique for resuscitation in cases of stillbirth. The same day that I read this article, while perusing the *Encyclopaedia Britannica* on quite a different quest, I found an article on "Rocking." This edition of the *Encyclopaedia Britannica* is dated 1896, and in this article is an account of a method ascribed to Dr Marshall Hall, who in 1856 described a method of resuscitation in cases of stillbirth and drowning which, although it is called "imitated breathing," in actual fact by description appears to be based on rocking the patient from a reclining position on the right side to a near proneness on the ground and returning, at some 15 rocks a minute. Although this article does not go into such detail as that of Drs Eve and Forsyth regarding the point at which recovery commences, the general description suggests that rocking as a means of resuscitation has an honourable ancestry. It is interesting that Dr Hall's method was supplanted by the more direct imitation of respiration used in the Silvester method. Are we now perhaps turning full circle?—I am, etc,

Oxford

V L KAHAN

SIR,—In 1917, while still a student, I served under Dr Frank Eve as resident medical officer at the Children's Hospital, Hull. At that time it was taught that the correct method of dealing with a case of asphyxia neonatorum was by throwing the child (still retaining a hold by the ankles) over the shoulder at intervals until the child showed signs of breathing properly.

Surely this method (in later years ridiculed by authoritative teachers) would have had the effect of rocking the cerebral blood onwards and so have produced the same result as in Dr Eve's rocking method. He states that steep angles when rocking are presumably best, so that the old method of throwing over the shoulder could be considered as an actual improvement on Dr Eve's method—I am, etc,

South Shields

S E GOULSTINE

### Genu Valgum

SIR—In reference to Mr H A Brittain's article (Aug 21 p 385) on genu valgum follow-up of children from birth to say sixteen years of age suggests that without treatment the same child at different stages may appear knock-kneed or bow-legged before finishing to all appearances normal. It also suggests that relative laxity of the lateral ligaments is usual with or without any apparent deformity.

I have also the impression that apparent genu valgum is more common in children who are going to be taller than average and the reverse appearance in the more stocky type. Could it not be that the condition is due (in some cases) to a faulty correlation in time between the alteration in the tibio-femoral angle from infant's to adult and the alteration in the femoral neck angle with relative broadening of the pelvis which takes place during the same period?—I am, etc,

Dorset

H A LAVELLE

### Purpura Complicating Scarlet Fever

SIR—I should like to add one point to those mentioned by Drs T Anderson M S Ferguson and J B Landsman in their paper on purpura fulminans complicating scarlet fever (Sept 18 p 549). Besides the purpura occurring eleven days after scarlatina their case showed gastro-intestinal symptoms (haematemesis, colic, melaena), joint symptoms (painful swellings of the joints) and nephritis (haematuria, cylindruria). In these respects their case resembles several of the previously reported cases of post-scarlatinal purpura from which it is clear that

post-scarlatinal purpura is a particular example of the Schonlein-Henoch syndrome (anaphylactoid purpura).

The interest of cases such as that reported is that they illustrate clearly the fact that aetiologicaly the Schonlein-Henoch syndrome belongs to that family of diseases which includes acute nephritis and rheumatic fever and which is characterized by the relation of these diseases to a preceding streptococcal infection—I am, etc,

Cambridge

DOUGLAS GAIRDNER

### Reactions to Intravenous Sclerotics

SIR—With reference to Dr C E Taylor's letter (Sept 18, p 573) describing two cases of allergy to the use of sodium morrhuate as an intravenous sclerosant, I am surprised that this substance is still being used having regard to the large number of cases on record of allergic responses ranging from urticaria to death. Monoethanolamine oleate has long been recognized as a safe substitute for sodium morrhuate and is bacteriostatic. It is marketed under several trade names. Rowden Foote<sup>1</sup> discusses this angle very thoroughly in his book on the subject, and refers to the writings of Mr Harold Dodd, who in 1940 stated that sodium morrhuate was potentially dangerous as well as being an inefficient sclerosant. I feel that the views of these two authorities cannot be too widely known—I am, etc,

Ortery St Mary Devon

R E SIDEBOTHAM

### REFERENCE

<sup>1</sup> *Varicose Veins, Haemorrhoids and Other Conditions—Their Treatment by Injection* 1944 London

### Transfusion and Haemolytic Disease

SIR—In their paper on transfusion as a cause of haemolytic disease Drs George Discombe and H O Hughes (Aug 14 p 329) state that a history of transfusion without Rh testing is 18 times more common among mothers of infants suffering from haemolytic disease of the newborn than among unselected patients at an antenatal clinic.

It may put the matter into perspective if we calculate the chances of an untransfused mother having an infant with this disease as against those of a transfused mother. On the figures given in the article 36% of mothers of infants with the disease had been transfused, while only 2% of a random sample of clinic mothers had been transfused.

Assuming that x% of transfused mothers and y% of untransfused mothers have infants suffering from the disease,

we get 36 such infants from  $\frac{36 \times 100}{x}$  transfused mothers at

risk, and 64 such infants from  $\frac{64 \times 100}{y}$  untransfused mothers

at risk. As 2% of mothers attending the clinic have been transfused and 98% have not,  $\frac{3,600}{x} = \frac{2}{98} \times \frac{6,400}{y}$  and therefore

$x = 27.56 y$ . That is, a woman's chance of having an infant suffering from haemolytic disease of the newborn is more than 27 times increased by having a blood transfusion first, if not Rh-matched for her before administration.

If the statistics given by the authors can be accepted as representative which I see no reason to doubt Drs Discombe and Hughes have drawn attention to a risk which most doctors have not until now realized and which we should certainly not forget—I am, etc,

Shipton, Yorks

H S RUSSELL

### Poisoning by Berries

SIR—Reports of poisoning by berries are becoming alarmingly frequent. The following two cases show how vital it is that the public at large should be made aware of the danger, as this knowledge may make all the difference to the result.

A boy aged 6 years told his mother on returning home that he had been eating berries. The mother, fortunately understanding the grave possibilities, immediately called in her family doctor who brought the child to hospital. On admission there were no symptoms or signs of poisoning. The stomach was washed out, and in the stomach washings berry residues were found. The patient was further given an emetic and a saline

The child then stated that a little girl had been with him and had also eaten berries. She was traced and brought to hospital about one hour later. She too was symptomless, but many berries were found in the stomach washings. By retracing the route taken by the children, a bush covered in woody nightshade was found. The berries on this bush were identified with those found in the stomach washings. The two children were observed for 48 hours in hospital, but developed no untoward symptoms. It is obvious that only prompt action by the boy's mother and by the family doctor prevented a very serious accident.

As the symptoms of poisoning by woody nightshade are those of paralysis of the respiratory muscles, it would seem that a mechanical respirator may afford the most rational line of treatment in tiding them over the stage of respiratory paralysis—I am, etc.,

London N 21

P R DAVIS

### Rhabdomyosarcoma of the Urinary Bladder

SIR—The striking characters of the tumour described by Mr Claude Vipond in your issue of Sept 18 (p 551) prompt me to add a further detail from the necropsy report of the case.

The growth appeared to have invaded the bladder from the outside and had ulcerated through its posterior wall, sections from this region supported this observation. The prostate gland was not identified in the tumour, whose anatomical relations were necessarily disturbed by its great size.

I understand Mr Vipond returned to Canada some time before this article was published—I am, etc.,

Dudley

A G MARSHALL

### Empirical Methods

SIR—Now that the difficult cases which once gave zest to a country doctor's life are passing more and more out of his hands it might be a boon to find some fresh interest that would redeem him from the life of an obedient clerk. May one not unfamiliar with the laboratory offer a gleam of hope? I suggest that a harvest lies waiting for people with the faith and judgment to collect sift, and co-ordinate empirical methods of treatment—unknown to and despised by rational scientists—methods driven by ridicule from orthodox practice for, without minimizing in the least the good that organized science has done and will do for the sick, we are surely beginning to doubt the Victorian doctrine of its all sufficiency. In medicine as in other walks of life two other legs of the tripod still have their uses—namely direct empirical knowledge handed down by custom, and one's individual experience and clinical sense. Everyone knows that the three in balanced combination are a safer support than any one taken alone.

Be that as it may one cannot fail to observe unpleasant side-effects of an undiluted rationalism: (1) the growing complexity of accumulated and sometimes irrelevant facts the memorizing of which robs young novices of health and recreation, (2) the mounting expense of analyses applied indiscriminately to the public at large, (3) that while rational medicine sheds healing light on some disorders it leaves the treatment of others in blacker darkness than before particularly the residue which the G.P. has to deal with once the 'interesting' cases have gone elsewhere, (4) the authoritarian view that it is more respectable to try remedies that 'ought' to work but do not than those which ought not to work but do, (5) a lowered prestige of the profession in the eyes of pharmacists, who notice our lost inventiveness and lost elegance in composing and handling simple medicines.

Illnesses have vexed mankind since the Garden of Eden, and unless he experience of the ages counts for nothing beside that of this century I make bold to suggest that a fraternity of hand-picked doctors on the lines of a mediaeval guild and unhampered by official control could do the profession a good turn by testing and reassessing remedies and customs, tips and wrinkles which have died out either with their humble originators or with the school that bred them. If some direct and simple but forgotten remedy can heal *cito tute et jucunde* why not resurrect it and leave the underlying reason to be worked out by science at leisure?—I am, etc.

Wellington Salop

A R MCCLURE

### Comprehensive Child Health Service

SIR—Reference the letters which have appeared in the *Journal* under this heading, the following conditions are required for a complete child health service: (a) team work, (b) a recording system giving each child a complete dossier, (c) the new health centre. No doctor can deal single-handed with child health in all its aspects, but the family doctor must be the central figure in the scheme, and it will be through him that the various measures can be co-ordinated and through him that the full co-operation of the parent is obtained. Child health begins in the antenatal period, and preventive measures are continued in the child welfare and school clinics. It is essential to have the full support of the family doctor in this preventive work. The prevention of T.B. infectious diseases, rickets, rheumatism, and nutritional and mental conditions will require attention.

Physical defects occurring during this period and requiring curative treatment must be dealt with by the family doctor and/or specialist. The team required therefore is the family doctor, M.O.s of the preventive clinics, and the specialists. The child's dossier will include all records of the various members of the team and give details of the preventive and curative measures taken from the antenatal period onwards. These records will be available to each member of the team.

To develop such a scheme to the full implies the development of the new health centre, where all clinics and consultations come under the one roof and the records are available as required. I emphasize that the family doctor must be the central pivot of the scheme. He is in direct touch with the parents and in their confidence, and it is he who will advise on the preventive and curative measures in the health of the child—I am, etc.,

Southport Lancs

S T BEGGS

### POINTS FROM LETTERS

#### Traumatic Amputation

DR E PROTHOROE SMITH (Credon, Devon) writes. The medical memorandum by Dr J D C Millar (Sept 18, p 559) reminds me of what must be a very rare accident. A man's clothing was caught in some machinery he was working on, and he was swung round the shaft till he fell dead. On arrival shortly afterwards I found his left leg completely torn off and the left side of the pelvis had gone with it, separation having taken place at the pubic and sacro iliac articulations. I do not remember (after 25 years) at what level the nerves and vessels were torn but the ureter was torn, both ends being seen the upper still dripping urine. The amazing thing was that the peritoneum remained intact and clean of fasciae and muscles, and the contents (bowels and bladder) could be easily seen through it.

#### Fibrositis and the Weather

Squadron Leader A T RYLAND (RAF, St Athan, Glamorgan) writes. Dr G C Pether points out in his letter (Sept 18, p 573) that fibrositis is a very real affliction to those who suffer from it, and he suggests that "weather pains" are not directly due to changes of humidity, pressure, or temperature. Anyone with access to a hygrometer, barometer, or thermometer can verify that patients can predict weather changes before these instruments vary their readings. Also there is no need to experiment with artificial climates. Going from a dry, cold room into a warm, steamy bathroom going up or down stairs (or better still climbing a hill), and going from a warm room to a cold one, will produce the respective changes required and will be found to have no effect. Nor does the old 'let out'—If you can't explain it, blame it on electricity—work in this case. The difference of potential between different levels of the air is a very variable quantity and is liable to sudden changes, as during rain. These changes are not reproduced in the patient.

In spite of these difficulties I have been able to find a connexion between these pains and the weather. A meteorologist, by drawing a weather map, can tell you that to-morrow a warm front will pass and you will feel warm. In the same way, by inspection of a weather map I can predict the onset of 'weather pains'. But in spite of that I have not the slightest idea how the influence is transmitted from the approaching weather to the patient. I can make only the weak suggestion that like homing pigeons some human body may possess an extra sense over and above the normal six which makes them susceptible to meteorological influences. There is an interesting field for research here.

## DIGOXIN 'B.W.&CO.'

BURROUGHS WELLCOME & CO. (INCORPORATED) LONDON

The diagram summarizes the local and central actions of the drugs contained in 'Franol'. Clinical experience indicates that the combination gives more effective control than ephedrine and theophylline prescribed singly.

A noteworthy function of the 'Luminal' content is to allay anxiety. It keeps the patient physically and mentally at ease, inhibiting the sudden panic which sometimes precipitates an emergency call.

*FRANOL* (Cephalidine 4, theophylline 4, Luminal) is supplied in packets of 20, 100, 500 tablets. The average adult dose is 1 tablet t.d.s. or 1-2 at the first warning of an attack.

BAYER PRODUCTS LTD AFRICA HOUSE W.C.2

## Analgesia from a travelling case

The Minicase is designed to meet the needs of visiting practitioners and midwives alike.

Now standard throughout Great Britain. It weighs only 15 lbs. in its travelling case, measures 19" x 12 1/2" x 5" and is specially designed for self-administration by the patient. The flow of gas is controlled by the patient's own respiration. Complete unconsciousness never occurs as on the verge of insensibility the pressure of the patient's finger relaxes allowing additional air to enter and dilute the mixture. Muscular action remains un-

impaired. A wheeled model for hospitals and nursing homes is also available.

## Obituary

DR FRANCIS KEENE MARRIOTT died on Aug 30 at the early age of 55 after an illness of several months duration. At times he suffered attacks of most intense pain which he bore with great fortitude, and to the very last he hoped to be able to continue some of his work. He was educated at Gresham's School and trained at the London Hospital, qualifying in 1915. He served in the first world war in the R A M C, and was awarded the Military Cross for conspicuous bravery and devotion to duty. On his release from the Army he did several house appointments and then took up practice in Yoxford. Dr Marriott had an extensive rural practice, and was a general practitioner of the finest type. Soon he was deeply concerned with parochial affairs, and he was elected chairman of the parish council and its representative on the Blyth R D C. He was president of the British Legion and village club and a great supporter of the cricket and football clubs. Last year he became chairman of the Clinical Society of Ipswich. He had taken an active part in B M A work, and was elected chairman of the East Suffolk Division in 1938. He was always a wise and keen member of the East Suffolk Panel Committee, which he represented on the county council and recently at the Panel Conference in London. During the second world war he served as a major in the Home Guard and spent a lot of time teaching first aid in the Yoxford area. He also carried on the practice of an absent colleague, and was very overworked. As a physician at the Patrick Stead Hospital, Halesworth, he was especially interested in obstetrics. It was a bitter blow to him when it became necessary to leave his home with its beautiful park and garden in which he had spent so many happy hours with his wife and two daughters. He loved country life and when he could spare the time shot and rode with the best. Dr Marriott was buried in Yoxford, where he had worked so hard and efficiently for twenty-seven years. The large parish church was filled to capacity, and sitting among the crowd I felt how very worth while such a doctor's life had been.—D W B

## Medical Notes in Parliament

### Hospitals Endowment Fund

SIR JOHN MELLOR on Sept 21 moved that the regulations entitled the National Health Service (Control and Management of Hospitals Endowment Fund) Regulations, 1948, be annulled. These Regulations provided for control and management of the Hospitals Endowment Fund set up under the National Health Service Act, 1946. The fund amounted to something like £15,000,000, and represented donations made in the past to the voluntary hospitals. The Act of 1946 largely defeated the intentions of those benefactors, but the House had a duty to see the fund was well administered. The Regulations entrusted to the National Debt Commissioners the management of the funds invested. The Minister was entitled under the Act to make this provision, but had exercised his discretion in a misguided manner. He called attention to the use by the National Debt Commissioners of money belonging to the Unemployment Fund, and contended that the Commissioners had used this money to influence the stock market to accord with Government financial policy. He contended that this fund should be beyond the reach of Treasury control. Possibly the public trustee would be an appropriate person to take over the duty of administration.

MR DAVID RENTON seconded the motion. He said the sum of £15,000,000 mentioned was a disappointment because Mr BEVAN on the Second Reading of the Bill had said that something like £32,000,000 belonging to voluntary hospitals was to be used as a shock absorber between the Treasury, the Government, and the hospital administration. The House should be given some idea whether and how regional hospital boards would get their share of the fund, as Mr BEVAN had promised during the committee stage of the Bill. When Mr BEVAN had obtained the funds, members assumed that they would be used solely for the benefit of the hospitals. He suggested it would be better if the funds were kept in a pool where they would be entirely free from use by the Chancellor of the Exchequer, who might feel tempted to bolster up his financial policy.

MR GLENVIL HALL said the Act laid down that voluntary non-teaching hospitals should transfer to the Minister the funds

at their disposal. These securities were in process of being transferred, and it was the Minister's duty to put them into an endowment fund. The Minister had received £17,750,000, and a good deal more was to come, although he could not say how much. The securities would be held in the name of the Minister of Health and not by the Treasury. Investments other than Government securities would gradually be transferred into Government stocks. The Government had not used the Unemployment Fund to bolster up a cheap money policy, and the charge made by Sir John Mellor was completely false.

MR ASSHETON said the fund had been set aside to benefit the hospitals, and there might be occasions when the interests of the hospitals and of the Treasury and National Debt Commissioners might not be identical. Some other funds had been invested in securities the value of which had fallen by 20%. There might well be a permanent loss to those funds. The Opposition was trying to safeguard the Treasury and the Ministry of Health from making a similar mistake in regard to the Hospital Endowment Fund.

Sir John Mellor's motion was defeated by 183 to 40.

### National Health Service

SIR HENRY MORRIS-JONES was told by Mr BEVAN on Sept 23 that over 90% of the total civilian population were on the lists of doctors engaged in the National Health Service. Available figures might involve some duplication which could not yet be exactly estimated. The number of people who had not applied to go on doctors lists was, subject to elimination of duplicates fewer than 4,000,000 for England and Wales. The number who had asked for their names to be removed was not known.

MR BEVAN confirmed that regulations entitle foreign nationals on a short visit to Great Britain to full benefit under the National Health Service, including the replacement of dentures or spectacles. He added that the cost of treating aliens could not be estimated but was likely to be small.

MR BEVAN also indicated, in reply to a later question that he knew of the delay to thousands of persons in receiving optical benefits. As anticipated heavy initial demands were resulting in temporary delays, but increased production should soon close the gap. Persons entitled to the provision of free spectacle lenses under the National Health Service Act 1946, were permitted to have these lenses fitted to spectacle frames already owned by them.

**Capitation Fee**—Commander NOBLE asked on Sept 25 what capitation fee was to be paid to general practitioners under the National Health Service. Mr BEVAN replied that there was a total fund of 18s multiplied by 95% of the civil population. This was divided into local funds, on a basis agreed with the profession. Doctors shared it according to the people on their lists.

**Dental Estimates**—On Sept 23 Sir ERNEST GRAHAM LITTLE asked what was the cost to date of dental estimates submitted or approved by the Dental Estimates Board. Mr BEVAN replied that the Board had authorized payment of a total of £708,307 up to Sept 17. There was no excess over the sums already voted by Parliament for the purpose.

**Cost of Prescriptions**—The estimated cost of prescriptions dispensed from July 5 to Aug 5 was nearly £1,500,000. The amount paid from July 5 to Aug 31 (for which period alone figures are available) for sight testing and supplying glasses under the supplementary ophthalmic service was £237,433, though this figure did not represent the full liabilities incurred during the period. This information was supplied by Mr BEVAN to Sir HENRY MORRIS-JONES on Sept 23.

**Tons of Paper**—There have been distributed 13,200,000 copies of a leaflet on the National Health Service costing £4,350 and requiring 46 tons of paper. As regards the National Insurance Scheme 40,400,000 leaflets, including the family guide, were made available for distribution, costing £54,000 and requiring 424 tons of paper.

**A I D under N H S**—On Sept 23 Mr DRIBERG asked what facilities for artificial insemination were provided at clinics under the National Health Service, if such facilities included both A I (H) and A I (D), what information had been received from such clinics regarding the physical and mental health and development of children born as a result of artificial insemination, and if Mr BEVAN would make inquiries on this subject from private clinics. Mr BEVAN answered that no such facilities were provided. On the last part of the question he was not advised that such an inquiry would be justified.

## Medico-Legal

### SILICOSIS NOT AN ACCIDENT

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The tendency of the House of Lords to interpret the Workmen's Compensation Acts 'beneficially' has led to a number of decisions which have expanded the concept of injury by accident to an extent which puts a severe strain on both the imagination and the semantic sense of the ordinary person. In recent years this section of the *Journal* has contained some account of cases in which compensation was awarded to a workman who had contracted Raynaud's disease from the vibration of a rotary tool<sup>1</sup> and to another who suffered from hernia as a result of the vibration of a pneumatic drill.<sup>2</sup> 'The classical case on which these were based was that of a girl<sup>3</sup> who, after sustaining numerous cuts and scratches on her hands in the course of her work over a long period, ultimately became totally incapacitated as a result of blood poisoning. It was held that she was not the less entitled to compensation because her disease was due not to one specific and definite accident but to a series of accidents, each one of which was specific and ascertainable though its actual influence on the resulting illness could not be precisely fixed. The House of Lords seems now to have called a halt to this process.

A workman<sup>4</sup> contracted silicosis through prolonged work as a slate cutter. Because slate does not contain 50% of silica he could not benefit from the Silicosis Scheme. He therefore claimed for compensation for an injury by accident, arguing, as the former applicants had, that each particle of silica had caused a separate accident and that his condition was the result of the accumulation of these infinitesimal injuries. The House of Lords decided against him. The decision was doubtless influenced by the earlier case of *Williams v Guest* etc.,<sup>5</sup> in which a claim based on silicosis was rejected by the Court of Appeal on the ground that the illness was not due to an accident as that word is used in the Act, or to a series of accidents but was the result of a continuing process repeated from day to day. Lord Porter admitted that two types of cases had in the past not been sufficiently differentiated—those in which a single accident is followed by a resultant injury as in the

anthrax case<sup>6</sup> in which the entrance of an anthrax bacillus was the "accident", and those in which, as in the case of the girl with the cut hands, there was a series of specific and ascertainable accidents followed by an injury which might be the consequence of any or all of them. Although it was possible to analyse silicosis into a series of separate injuries caused by separate accidents the attribution of the disease to an accidental cause was he said, unreal. The distinction between accident and disease had been insisted on throughout the authorities and was well founded. No explicit formula could be adopted with safety but there must come a time when the indefinite number of so called accidents and the length of time over which they occurred took away the element of accident and substituted that of process. In his opinion, disability from silicosis was one of such instances and could not be said to be the result of injury by accident. Lord Simonds, who also gave an opinion quoted words recently used by Viscount Caldecote of three cases in which the workman failed because 'the facts were such as to make it impossible to identify any event which could however loosely be called an accident', and also Lord Romer's question 'Was there a physiological change for the worse in the respondents' condition on a particular occasion while he was at work?' He considered that the case of the girl with the scratched hands was the high-water mark (of the doctrine of cumulative injury by infinitesimal accident). Lord du Parcq added that the duty of construing an Act of Parliament was not to be performed by deducing from dicta contained in earlier judgments principles which might seem to follow from them.

## Medical News

### Medical Photography

There will be an informal display of medical photographic apparatus and records at the Department of Medical Photography, Westminster Hospital Medical School, 17, Horseferry Road, London SW 1, from Oct 5 to 9 inclusive (10 a.m. to 4 p.m.). Series of photographs will show the recording of complete case histories of dermatological conditions.

### Chartered Society of Physiotherapy

Mr Walter R. Owen, chairman of the London County Council, proposed the toast of the Society at a luncheon on Sept 24. He recalled the many activities of the physiotherapists since the time—about fifty years ago—when they were popularly known as rubbers and spankers, and paid tribute to their enlightened policy, especially in the field of education. The LCC was very appreciative of the Society's endeavours. Dr W. S. C. Copeman, chairman of council of the Society spoke of its future and suggested that, though temporary dilution of its ranks might be necessary owing to the shortage of physiotherapists, they must make sure that it was only temporary. The Society had offered to open a supplementary register and wished it to be officially recognized. He hoped for an answer from the Ministry of Health in the not-too distant future. Lord Horder, president of the Society, welcomed the guests and particularly the delegates from fifteen countries overseas. This meeting perhaps foreshadowed things to come—possibly an international body of physiotherapists. Dr C. E. Thackray Parsons, deputy master of the Worshipful Society of Apothecaries, said that, when he remembered in his youth the many people crippled with arthritis and other conditions and compared their treatment then with that given to day, he realized how much they owed to the physiotherapists.

### Hospital Admissions and Records

A report entitled "Some Observations on Hospital Admissions and Records" published under the auspices of King Edwards Hospital Fund (London George Barber Is.) emphasizes the advantages of having an appointment system at hospitals. A group of administrative officers studied the arrangements at eight hospitals on a short course established by the Fund and found that an efficient appointment system saves space and prevents overcrowded clinics. The best system is for all out patients (except at certain special clinics—for example V.D.) to have an appointment arranged by either the doctor or the patient unless referred from the casualty department; the patient must bring a doctor's letter or a note from casualty. The report advocates a central office for dealing with appointments, which should be allotted in half hourly or hourly blocks. Normally not more than 15 minutes should elapse before the patient is due to see the doctor. Cases suitable for teaching may be sorted out by the appointment clerks who are informed by the consultants of their requirements. The out patient department should provide only consultations and special treatment which cannot be given by the general practitioner cases that can be treated by the general practitioner may nevertheless be used for teaching purposes in casualty. A senior R.M.O. should be in charge of admission waiting-lists, since he can 'borrow' beds and the arrangements are therefore more elastic. The unit system of keeping notes—one number for ever, one folder, and one central index—was found to be the most efficient. Messengers must carry the notes from one department to another so that the patients shall not read them. Every hospital should have a records committee and an experienced records officer in charge.

### Smoke Abatement

Lord Simon of Wythenshawe has been elected President of the National Smoke Abatement Society. The retiring President, Sir George Elliston, chairman of the Public Health Committee of the City of London Common Council delivered his final presidential address on Sept 30 at the annual conference of the Society at Cheltenham, which was attended by over 400 delegates from local authorities and technical organizations.

### Insurance Agreement with New Zealand

A reciprocal agreement has been made between Britain and New Zealand covering the Government issue of family allowances in the two countries so that tests of residence will be waived for families coming from the other country. Under the New Zealand scheme 10s a week is paid for every child, including the first.

### International Orthopaedic Surgery

At the fourth congress of the Société Internationale de Chirurgie Orthopédique et de Traumatologie held in Amsterdam from Sept 13 to 18 the following officers were elected. President of the Society—Sir Harry Platt, vice-presidents—Dr San Ricart (Barcelona) and Professor E. Sorrel (Paris). The next congress will be held in May, 1951 at Stockholm with Professor Richard Scherb of Zurich as president of the congress.

**Royal Sanitary Institute**

Sir Weldon Dalrymple Champneys, Bt., will take office as Chairman of the Council of the Royal Sanitary Institute on Oct 1

**American College of Radiology**

Dr Russell Reynolds has been elected an honorary fellow of the American College of Radiology

**COMING EVENTS****British Congress of Obstetrics and Gynaecology**

The twelfth British Congress of Obstetrics and Gynaecology will be held at Friends House, Euston Road, London, N.W., on Wednesday, Thursday, and Friday, July 6, 7, and 8, 1949, under the presidency of Sir Eardley Holland. The Minister of Health will declare the Congress open at 10 a.m. on July 6, and a discussion, to be introduced by Mr C McIntosh Marshall (Liverpool), on "Modern Caesarean Section" will follow. At 2 p.m. a paper will be read by Dr Joe Meigs (Massachusetts), followed by a discussion on "Pregnanediol," to be introduced by Professor G F Marrian, D.Sc., F.R.S. (Edinburgh), and Dr G I M Swyer (London). On July 7 at 10 a.m., Professor G W Pickering and Professor F J Browne (London) will introduce a discussion on "Essential Hypertension in Pregnancy." At 2 p.m. discussions on "Hernia of Pouch of Douglas" and "The Management of Pregnancy in Diabetes" will be introduced by Mr C D Read (London), and by Mr J H Peel (London) and Professor D M Dunlop (Edinburgh) respectively. On July 8, at 10 a.m., Dr J E Ayre (Montreal) and Dr F G Spear (Cambridge) will introduce a discussion on "Diagnosis and Prognosis of Carcinoma of the Uterus." At 2 p.m. there will be a discussion on "Maternal Mortality." The honorary secretaries of the Congress are Mr A Joseph Wrigley, M.D., F.R.C.S., and Mr Ian M Jackson, F.R.C.S., and the names of those who hope to attend the Congress should reach them by March 31, 1949, at the latest, at the Royal College of Obstetricians and Gynaecologists, 58, Queen Anne Street, London, W.1

**Chadwick Public Lectures**

The Chadwick Trust (204, Abbey House, Westminster, London, S.W.1) announces the following public lectures: Thursday, Oct 7, 8.30 p.m., at the Reception Room of the University of Bristol, Mr A Briggs, "The Public Health Act of 1848—a Forgotten Centenary." Thursday, Oct 28, 4 p.m., at University College, University Park, Nottingham, Sir Arthur McNulty, "Advances in Preventive Medicine During the War of 1939-45." Tuesday, Nov 2, 2.30 p.m., at Sir Edward Meyerstein Lecture Theatre, Westminster Hospital Medical School, 17, Horseferry Road, Westminster, London, S.W.1, Dr Wyndham E B Lloyd, "The Prevention of Tuberculosis, with Special Reference to Environment." Tuesday, Nov 23, 2.30 p.m., at Royal Sanitary Institute, 90, Buckingham Palace Road, London, S.W.1, Bossom Gift Lecture by Mr Alister MacDonald, "The Influence of Hygiene on the Shape of Buildings." Thursday, Dec 2, 4.30 p.m., at St Mary's Hospital Medical School, Norfolk Place, Praed Street, Paddington, W.2, Malcolm Morris Memorial Lecture by Dr C Seeley, "Preventive Medicine and Clinical Medicine in Relation to the Public Health." Tuesday, Dec 14, 2.30 p.m., at Royal Society of Tropical Medicine and Hygiene, 26, Portland Place, London, W.1, Mr S E Finer, "The Rise and Fall of the First General Board of Health." Admission to the lectures is free, without ticket.

**International Scientific Film Congress**

In connexion with the International Scientific Film Congress to be held in London from Oct 8 to 12, the Scientific Film Association has arranged three morning meetings for viewing and discussing medical films, on Friday, Oct 8, at the Royal Society of Medicine (1, Wimpole Street, W.) with Sir Kenneth Goadby in the chair, on Saturday, Oct 9, at Simplot Ltd, 1-4, Lambeth High Street, London, S.E., with Dr Ronald MacKeith in the chair, and on Monday, Oct 11, at Royal Society of Medicine, with Dr E Goodwin Rawlinson in the chair. Medical practitioners and others in possession of medical and biological films which they are willing to send or bring to these meetings are asked to send details to the organizer of the Specialist Medical Sessions of the Congress at 34, Soho Square, London, W.1. Applications for admission to the meetings, which is free, should be made to the same address.

**National Hospital**

The inaugural address will be given by Dr Gordon Holmes, F.R.S., to open the academic year 1948-9, at the National Hospital, Queen Square, Institute of Neurology, London, W.C., on Oct 4, at 5 p.m. His subject is "Incoordination of Movement."

**Pharmaceutical Society of Great Britain**

The opening of the 107th session of the Pharmaceutical Society of Great Britain and the presentation of prizes will take place at 17, Bloomsbury Square, London, W.C., on Wednesday, Oct 6, at 3 p.m., when Mr Thomas Tickle will deliver the inaugural address.

**Annual Dinner of Officers of R A F Medical Branch**

The annual dinner of officers of the Royal Air Force Medical Branch will be held at the Dorchester Hotel, London, W., on Friday, Oct 8. The price of tickets (the number is limited) is £2 10s inclusive. Former officers who wish to attend the dinner should make early application to Squadron-Leader J W Garraway, Air Ministry M.A.1, Awdry House, Kingsway, London, W.C.2

**London County Medical Society**

The London County Medical Society will hold a meeting at Friends House, Euston Road, London, N.W.1, on Oct 7, at 3.45 p.m. A discussion on "Nutrition in Hospitals" will be opened by Dr Magnus Pyke, D.Sc., to be followed by Miss Simmons, dietitian of Hammersmith Hospital.

**Royal Dental Hospital of London**

The prize distribution and Conversazione of the Royal Dental Hospital of London School of Dental Surgery (University of London) will be held at the Royal Dental Hospital, 32, Leicester Square, W.C., on Saturday, Oct 9, at 3 p.m.

**Royal Photographic Society**

The second part of the 93rd annual exhibition of the Royal Photographic Society of Great Britain will be held at 16, Princes Gate, London S.W. from Oct 9 to 30 inclusive, and will include a number of exhibits of special interest to the medical profession.

**SOCIETIES AND LECTURES****Tuesday**

INSTITUTE OF DERMATOLOGY 5, Lisle Street, Leicester Square, London, W.C.—Oct 5 5 p.m. *The Dermatoses of Childhood* by Dr R T Bruin

SOCIETY OF CHEMICAL INDUSTRY FINE CHEMICALS GROUP—At Royal Institution, Albemarle Street London W., Oct 5 7 p.m. *Fine Chemicals for Medical Use* by Professor J H Burn

**Wednesday**

GLASGOW UNIVERSITY DEPARTMENT OF OPHTHALMOLOGY—Oct 6 8 p.m. *Physiotherapy of the Eye* by Mr F W Law

**Thursday**

CHADWICK TRUST—At Reception Room Bristol University, Oct 7 8.30 p.m. *The Public Health Act of 1848—a Forgotten Centenary* by Mr A Briggs

FACULTY OF HOMOEOPATHY—At London Homoeopathic Hospital, Oct 7 5 p.m. *The Three Constitutions* by Dr Leon Vannier (Paris)

INSTITUTE OF DERMATOLOGY 5 Lisle Street, Leicester Square, London W.C.—Oct 7 5 p.m. *Modern Trends in Dermatology* by Dr R M B MacKenna

ROYAL SANITARY INSTITUTE—At Ambulance Hall, St James', Pontypool Mon Oct 7 10 a.m. *Health and its New Aspects* by Dr A S Jarmann, *Food Hygiene* by Mr F G Meek

SOCIETY AND CLINIC FOR CONSTRUCTIVE BIRTH CONTROL AND RACIAL PROGRESS—At Mothers' Clinic, 108, Whitfield Street London, W., Oct 7, 2.30 p.m. *A doctors demonstration of contraceptive technique* by Drs Marie C Stokes and Beddow Bayly

**Saturday**

ROYAL DENTAL HOSPITAL OF LONDON SCHOOL OF DENTAL SURGERY (UNIVERSITY OF LONDON)—Oct 9, 3 p.m. Prize distribution and Conversazione at the hospital. Sir Walter Monckton will present the prizes

**BIRTHS, MARRIAGES, AND DEATHS****BIRTHS**

Bird—On Aug 31 1948 at Trafalgar House Burnley to Renee wife of Dr George Bird a son—Richard Edward  
MacLeod—On Sept 21 1948 at Clevedon Somerset to Noreen wife of Dr Alastair MacLeod a daughter  
Mardin-Scott—On Sept 18 1948 at The Old Farm Maternity Home Temple Sheen S.W. to Nancy (née Pepper) wife of Dr Ian Martin-Scott a son  
Oliver—On Sept 20 1948 at Annandale Nursing Home to Helen Taylor wife of Dr R M Oliver a daughter  
Pearce—On Sept 15 1948 at Nuffield House London S.E. to Margaret (née Gibson) wife of Dr Richard Pearce a daughter  
Salmond—On Sept 12 1948 to Elsa wife of Dr J Readdie Salmond Lindores Appleby Magna Leicestershire a daughter—Madeline Rosemund

**DEATHS**

Boulton—On Sept 19 1948 Norman John Boulton M.R.C.S. L.R.C.P. of Kimbury Berkshire aged 45  
Cantillon—On Sept 6 1948 Edwin Vincent Cantillon of Rose Lodge Blackrock Cork  
Gibson—On Sept 16 1948 Harold Edward Gibson M.D. of Upcott, Old Beer Road Sutton Devon late of South Godstone Surrey  
Henry—On Sept 17 1948 John Rea Henry M.B. B.Ch. B.A.O. of The Limes Baby Leicestershire aged 64  
Walker Lindsay—On Sept 19 1948 Edythe Marjorie Stewart Walker Lindsay M.B. Ch.B. Glas. of Pitchfield Cottage Thursley Surrey formerly of Aldershot

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept 11

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland  
 Figures of Births and Deaths and of Deaths recorded under each infectious disease are for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland  
 A dash — denotes no cases a blank space denotes disease not notifiable or no return available

Disease	1948					1947 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)

Deaths (0-1 year) Infant mortality rate (per 1 000 live births)	260	32	52	26	10	316	37	63	31	17
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	3 840	578	527	177	108	3 678	558	490	134	123
Live births Annual rate per 1 000 persons living	7 565	1 157	834	450	207	8 266	1 279	949	447	242
Stillbirths Rate per 1 000 total births (including stillborn)	185	25	33	—	—	210	24	26	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales (London (administrative county)) will no longer be published.

‡ Includes primary form for England and Wales (London (administrative county)) and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales (London (administrative county)) are combined.

¶ Includes puerperal fever for England and Wales and Eire

## EPIDEMIOLOGICAL NOTES

## Poliomyelitis in the United States

An incidence in the United States of 983 cases of poliomyelitis for the week ended July 24 exceeded by 315 that for the corresponding week of 1946—the year of second highest prevalence (25,191 cases) in the country's poliomyelitis history. It was also the largest number reported for a corresponding week in the five years period 1943-7 for which the median figure was 369. According to the *Weekly Epidemiological Record of the WHO* (Sept 8) between March 20 (average date of seasonal low incidence) and July 24 of the current year, three States—North Carolina 868, Texas 857, and California 771—have reported 2,496 cases, or approximately 59% of the total of 4,235 for the period. For the corresponding period of 1946 the total was 2 789 and the five year median 1 653. In 1946 the abnormal increase had been first observed in the early part of May and since that time the cases reported had been, until July 24, consistently about twice as high as the median frequencies for the period. The present epidemic appears to be fairly well localized, but its progressive upward trend is reflected in the subjoined weekly figures of recent incidence, which compare the case incidence in corresponding weeks of 1946 and 1948.

1946	Week ended	Cases	1948	Week ended	Cases
July	6	309	July	3	362
	13	427		10	511
	20	668		17	717
	27	670		24	983
Aug	3	1 286		31	1 215
	10	1 582		7	1 239
	17	1 819		14	1 411
	24	1,808		21	1 307

## Discussion of Table

In England and Wales a decrease in the number of notifications was reported for measles 354 and whooping cough 119 and an increase was recorded for scarlet fever 99, diphtheria 31, dysentery 20, paratyphoid fever 21, and typhoid fever 19.

A small rise in the incidence of scarlet fever occurred throughout the country. The chief feature of the returns for diphtheria was an increase of 24 in Lancashire, this was mainly due to a rise of 19 in Liverpool C.B. A fall in the incidence of measles occurred in most areas, the only large exception to the general trend was a rise of 95 in Lancashire. The fluctuations in the local trends of whooping-cough were small, the chief exception was a decline of 83 in the cases notified in Yorkshire West Riding.

An outbreak of typhoid fever affecting 20 persons was notified in Shropshire, Oswestry R.D. This outbreak has been confined to the Orthopaedic Hospital where it originated (Sept 18, p 582), and 51 inmates had been attacked up to Sept 21. In Staffordshire, Smethwick C.B., 10 cases of paratyphoid fever were notified. The largest returns of dysentery were Lancashire 21, London 12, and Yorkshire West Riding 12.

The incidence of acute poliomyelitis has remained constant during the past four weeks, and the chief centres of infection during the week were Lancashire 8, London 7, Yorkshire West Riding 6 (Sheffield C.B. 3), Gloucestershire 6 (Bristol C.B. 6), Glamorganshire 5, Middlesex 4, and Wiltshire 4.

In Scotland increases were recorded in the notifications of whooping-cough 24, scarlet fever 22, measles 16, diphtheria 14 and dysentery 12, while the notifications of typhoid fever were 11 fewer than in the preceding week. The rise in the incidence of diphtheria and dysentery was mainly contributed by the city of Glasgow. The increase in scarlet fever was due to a rise throughout the western area, 29 more cases were notified in this region than in the preceding week.

In Eire the largest return for scarlet fever was that of Dublin C.B., where 41 of the 55 cases were notified. An outbreak of measles in Clare Kilrush R.D. accounted for 20 of the 28 notifications. The largest return for whooping cough was 14 in Kildare Athy No. 1 R.D.

In Northern Ireland the decline in scarlet fever was due to the experience of the country districts, in the county borough an increase of 9 was reported. A decrease of 14 was recorded in the number of notifications of measles from Belfast C.B.

## Week Ending September 18

The notifications of infectious diseases in England and Wales during the week included scarlet fever 925, whooping cough 2 635, diphtheria 126, measles 2 614, acute pneumonia 28, cerebrospinal fever 26, acute poliomyelitis 72, dysentery 50, paratyphoid 17, and typhoid 28.

## Any Questions?

*Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.*

### Treatment of Chronic Nephritis

**Q**—What is the latest treatment for chronic nephritis (Ellis Type II)? Are there any drugs of real value?

**A**—There is no known curative treatment for Type II nephritis. Prognosis in general is bad, but with a normal blood pressure complete recovery is possible. High protein low-salt diet is the stand-by in the attack on oedema. Intravenous protein is usually very temporary in effect. Mercurial diuretics are not contraindicated if renal function is good but are not usually very effective. The body will not retain water without an equivalent retention of sodium. The volume of fluid ingested is therefore relatively unimportant provided that salt is restricted, and a high fluid intake may actually assist in procuring sodium depletion. The high-fluid low-salt regime advocated by Schemm is therefore sometimes very successful in getting rid of oedema. It consists in the administration of 7 pints (4 litres) of water or watery fluid daily by mouth while continuing a diet as nearly salt free as possible. In favourable cases a large diuresis occurs in a few days and is accompanied by reduction in the oedema. The regime may be continued as long as oedema is present.

### The Kempner Rice Diet

**Q**—What is the Kempner rice diet for hypertension? Is it of any value?

**A**—Walter Kempner distinguishes between affections of the metabolic and of the secretory functions of the kidney. In the latter hypertension, retinopathy, and rise of non-protein nitrogen occur. These changes, he postulates, are due to the accumulation in the blood of abnormal substances which in normal circumstances arise only as intermediary products in the metabolism of the kidney cells. These may be reduced by a rigorous diet consisting only of rice, fruit juices, and sugar, supplemented by vitamins and iron. The diet of 2,000 calories consists of 20 g. of protein, 5 g. of fat, 460 g. of carbohydrate, 0.2 g. of sodium and 0.15 g. of chloride. The fluid intake is usually limited to 700–1,000 ml. of fruit juices daily (no water). The average patient can eat 300 g. of rice daily, which will provide about 1,050 calories. The remaining 900–1,000 calories are obtained from extra sugar or fruit. All fruits are permitted except nuts, dates, avocados, and any dried or canned fruit to which substances other than sugar have been added. No salt is permitted usually, but patients with symptoms of salt deprivation are given extra sodium chloride in small amounts or hydrochloric acid. The patient is also given a minimum of vitamin A 5,000 units, vitamin D 1,000 units, thiamine chloride 5 mg., riboflavin 5 mg., niacinamide 25 mg., calcium pantothenate 2 mg., ferrous sulphate 0.6 g.

Kempner claims remarkable results in chronic renal disease and in hypertension. The blood pressure falls to normal, the heart diminishes in size, the ECG reverts to normal, the blood urea and cholesterol approach normal, and retinal changes regress. He emphasizes that the diet must be adhered to in every detail extremely strictly. This diet is very unpalatable but his patients have been on it as long as thirty months. He treats cases of all grades of severity, and his results are roughly death, about 25%, no change, about 25% improvements to remarkable degrees, 50%. No reports of the effectiveness of the diet have been made in England.

### Bronchial Carcinoma and Smoking

**Q**—Is there any relation between smoking and bronchial carcinoma? If so is cigarette or tobacco smoke or are both implicated?

**A**—There is as yet no proof of a causal relation between the incidence of bronchial carcinoma and the habit of smoking. On the other hand, the recorded increase in pulmonary cancer over the past thirty years or so is remarkable in being quite

unrelated (in contrast with the incidence of many other forms of cancer) to social status. This suggests that the factors responsible for the increase are environmental in nature and such as would affect every class of the population. Among such factors the concomitant general increase in tobacco consumption, particularly in the form of cigarettes is undoubtedly one which requires serious attention. What is the order of its importance, if any, and how this compares with the significance to be attached to other factors under suspicion, such as chemical contamination of the atmosphere from tarred road surfaces or from exhaust gases, are still matters for carefully planned survey both in the field and by experiment. Several such investigations have in fact already been inaugurated.

### Calcium Iodide for Cataract

**Q**—Is calcium iodide of any value in the control of cataract? What type of base is used? What is the dosage? How is it applied and over what period should it be used?

**A**—The use of iodides in the form of either sodium potassium or calcium salts by various local applications has no sound basis. There is a mass of confused argument which incriminates with equal lack of validity deficiency in either the metal or the iodine. Clinically these substances have been used for many years now in vain attempts to control the development of cataract, and most clinicians regard them as mere placebos.

### T A B Inoculation of Infants

**Q**—A patient will be travelling to either Malaya or Hong Kong with her husband and baby in October when the baby will be about 4–5 months old. Apart from routine vaccination will the baby require any immunizing injections? The mother will need only T A B (not as in the war cholera plague and typhus vaccines). Is immunity conveyed by breast milk? If not could you tell me what injections will be required and what the strength should be?

**A**—Babies who are breast-fed rarely, if ever, require T A B. It is probable that immunity is conveyed through breast milk. The question of immunization need not be considered till the baby is at least 18 months old. Children of 18 months have been given two or three doses each of 0.1 ml. with very slight reactions.

### Thrombophlebitis and Muscular Effort

**Q**—A patient developed thrombophlebitis of his right internal saphenous vein. While lifting stones at work he felt a sudden pain in his right groin on straightening up and on examination I found a reddening over the course of the saphenous vein. The vein was cordlike and tender with some oedema of the leg. He had no history of varicose veins and complete physical examination revealed no abnormality. As the case involves a claim for compensation I would like to know if his work was a factor in the production of his condition.

**A**—Phlebitis is not produced by muscular effort but a blow on the veins, especially if it ruptures the vein is likely to produce a phlebitis, particularly when a diathesis exists. It is likely that in this case there was a bland pre-existing phlebitis which was brought to the patient's notice by muscular effort. It would be hard to establish a compensation claim in this case.

### Light Sensitization Dermatitis

**Q**—What is the best treatment for severe light sensitization dermatitis? I have attempted to obtain special light-repelling face powders without success.

**A**—Treatment in these cases depends almost entirely upon effective protection from light by adequate clothing, including hats, gloves, stockings, etc., and by the use of protective creams on the exposed skin. Where the reaction is entirely urticarial control is often secured by the administration of antihistamines internally. Valuable protective measures are calamine titanium dioxide, ichthyol, quinine tannate, soft paraffin, and para-aminobenzoic acid. A calamine or titanium foundation lotion with a 2% ichthyol face powder is effective in mild cases, 4% quinine tannate or 15% para-aminobenzoic acid in a base containing equal parts of soft paraffin in Halden's emulsifying base are suggested in more severe cases, or equal parts of "siccolam," Halden's emulsifying base, and soft paraffin. In some cases sensitization is determined by a focus of infection the treatment of which may effect a cure.

## Offspring of a Syphilitic Mother

**Q**—What treatment if any should be given to a healthy 8 weeks old baby whose mother's Wassermann reaction is still weakly positive? The mother aged 26 had a positive W R during pregnancy and was confirmed still positive despite treatment with mercury and bismuth injections. Arsenicals upset her badly so were stopped. Treatment had started in the fourth month of pregnancy. The child shows no sign of syphilis and is thriving.

**A**—On the information provided there is no indication for treating the baby. It would be helpful to know what the baby's serum reactions are now, and what stage the syphilis of the mother had reached when she became pregnant or when the treatment was started. The older the syphilis in the mother the less likely is the baby to have been infected. Mercury and bismuth would hardly protect the baby from infection if the mother had secondary syphilis. It seems a pity she was not given penicillin. The procedure advised is to test the baby's blood and start treatment only if it is positive to the W R and Kahn test and tends to show a persistently high or rising titre over a period of several weeks. Quantitative tests should be employed. Should treatment of the baby be necessary, it should consist of an initial course of penicillin in oil-wax (100 000 units daily for ten days) followed by weekly injections of sulpharsphenamine and bismuth in gradually increasing doses calculated according to body weight.

## Radioactive Iodine in Thyrotoxicosis

**Q**—Radioactive iodine is being used in the treatment of thyrotoxicosis. Can you tell me the position of this remedy in the light of experience to date? The patient I have in mind is a man of about 60 with exophthalmos and a B M R which shows a toxicosis of moderate severity. He has shown some improvement after four weeks thiouracil medication. The pulse has come down from 90 to 78 and he has been ambulant throughout.

**A**—Radioactive isotopes of iodine have recently been used in the treatment of thyrotoxicosis, those chiefly employed have been  $I^{130}$  (half-life 12 hours) and  $I^{131}$  (half-life 8 days). Good results are claimed and "cure" is said to follow one oral dose in 90% of patients. It is fair to say that the method has not yet emerged from the experimental stage, and, in this country at any rate, radio iodine is not generally available. The practical disadvantage at present seems to be that the half-life of the isotopes is so short that they must be administered within four hours of production. In the particular example cited thiouracil has scarcely been given a fair trial but even in this short time improvement seems to have been considerable.

## Head Colds in a Child

**Q**—Would it be permissible to attempt to reduce the incidence of severe head colds in a child aged 5 in whom no pathological cause can be found in the ears, nose or throat by giving small daily doses of sulphadiazine throughout the winter?

**A**—The most likely aetiological agent of the common cold is a virus consequently the use of sulphadiazine would not be justified as a prophylactic measure. There would seem to be three possible causes for the trouble: first, there may be a chronic carrier (i.e. old sinus trouble) in the family. Recurrent upper-respiratory-tract infection in children is sometimes cured by taking out father's tonsils. Secondly, the child may have some pathological condition which has been missed, such as nasal infection. Thirdly associated with both of these, immunity may be low and might be stimulated by the use of a suitable vaccine and by general measures such as a full vitamin dosage, fresh air, and attempts to harden the child. The possibility of an allergic rhinitis should not be overlooked.

## "Dynamite Headache"

**Q**—What is the pathology and treatment of dynamite headache?

**A**—Dynamite largely used for blasting purposes in mines, is a mixture of nitroglycerin and the infusorial earth kieselguhr. Physiologically the action of nitroglycerin is that of a nitrite and it acts directly on the arterial muscle producing a prompt

fall in blood pressure. Given medicinally in therapeutic doses, within two minutes it accelerates the pulse, dilates the arteries, and produces a feeling of fullness all over the body, but particularly in the head. Headache may be caused lasting from 15 minutes to several hours, according to the quantity taken, but in patients accustomed to its use this effect may not be felt. In the manufacture of cordite some workers may experience headache due to nitroglycerin, and such effect is influenced both by the conditions of work and by the amount and duration of previous exposure—workers tending to become temporarily acclimatized. The treatment of headache from nitroglycerin and allied compounds is first to remove the sufferer to fresh air. If the headache continues, caffeine citrate, 2 gr (0.13 g) can be given. An alternative treatment is with aspirin, 5 gr (0.32 g), followed by ephedrine  $\frac{1}{4}$  gr (16 mg). Chronic poisoning has resulted from the taking of ephedrine over a period, and this drug should only be given under medical supervision. Nitroglycerin acts more quickly on an empty stomach so it seems advisable that workers exposed should partake of breakfast first.

## NOTES AND COMMENTS

**Colour Photographs**—Dr PHILIP ROSS has asked us to state that the colour films which were used to illustrate his article on "Skin Lesions due to Pitch and Tar" (Aug 21, p 369) were the work of Mr H. H. Tait, to whom he is indebted.

**Delivery after Operation for Prolapse**—Mr R. M. CORBET (Preston) writes. In "Any Questions?" (Sept 18, p 583) the problem of vaginal delivery following an operation for prolapse was considered. In the answer one complication has been overlooked—namely, traumatic post-partum haemorrhage. There is a small but definite chance of this occurring in any patient who has previously had an operation on the cervix. I have met this complication on two occasions, and therefore I am of the opinion that such patients should not have the first confinement after operation at home.

**Dangers of Cinchophen**—Dr EWAN F. B. CADMAN (Liverpool) writes. I would like to comment on the recent replies given in connexion with the questions on the dangers of cinchophen ("Any Questions?" Aug 28 p 450 and Sept 18 p 584). It is felt they are somewhat misleading. First, it is agreed that cinchophen is probably the most effective substance in increasing the excretion of uric acid but acetylsalicylic acid gives precisely the same beneficial results clinically and biochemically without the fear of serious complications (Bauer, W., and Klemperer, F., *New Engl J Med* 1944 231, 681). Toxicity of cinchophen is unrelated to dosage or previous medication, and once the symptoms have appeared, in the case of liver damage, poisoning progresses despite the discontinuance of medication. The incidence of serious toxic reactions is admittedly low, but up to 1936 as many as 191 cases of liver damage had been reported, with a mortality rate of 47% (Palmer W. L. and Woodall, P. S., *J Amer med Ass* 1936, 107 760). Other serious though not fatal complications are peptic ulcer, haematuria, and granulopenia—all rare.

Probably the most important part of the question was not answered—"Can you suggest any safer alternative?" If cinchophen were an indispensable drug like morphine, then there is little doubt that it should be used in spite of its occasional toxic effects. The complications of untreated gout may lead to an untimely death. However, there are excellent alternatives in the form of large doses of aspirin in chronic gout and colchicine in acute gout. Therefore, on general therapeutic principles alone, I feel very strongly that cinchophen should not be used in gout, or in any other condition unless there is some very good reason for its use.

**Correction**—Messrs Henry Kimpton inform us that they are the English agents for the book *Practice of Allergy*, by W. T. Vaughan and J. H. Black ("Books Received," Sept 25, p 604), and that the price is 75s.

# SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY OCTOBER 2 1948

## NATIONAL HEALTH SERVICE FIXED ANNUAL PAYMENT OF £300

the time of the April plebiscite the Council of the British Medical Association issued a document to every member of the profession setting out the changes which the Minister proposed to make in the National Health Service Act in response to the profession's representations. In this document (*Supplement* April 24, p 105) it was reported that the universal basic salary would be abandoned and that the Minister intended to limit it to principals during the first three years of practice, with an option to all other principals. Where basic salary was agreed, capitation remuneration would be reduced by one-seventh.

The Minister further agreed to discuss with the profession the conditions and methods of opting, so as to meet the Association's points, that basic salary should be paid only where there was need and, except in such circumstances, should not provide a means of opting for higher remuneration per patient.

The fixed annual payments of £300 are credited to the recipients as a first charge on the local pool allocated to each executive council. This means that wherever a basic salary is paid to a practitioner with less than 2,200 public patients on his list an additional payment is being made to such a practitioner by his colleagues in the area.

### Reasonable Justification

After further discussions with the Ministry the regulations relating to the grant of basic salary were amended to provide that the local executive council, after consultation with the local medical committee, must decide on every application whether there was reasonable justification for a basic salary. The Minister has given his view of what 'reasonable' means in the following extract from para 4 of E.C.L. 44, issued on July 2 to local executive councils:

'The new regulations also indicate the conditions of payment of the fixed annual amount of £300. The payment will be made only to those doctors who elect to have it and who receive the consent of the executive council (after consultation with the local medical committee) or, on appeal, of the Minister. (When the fixed annual payment is made the capitation fees will be adjusted as indicated in paragraph 3 (b) of the Memorandum on the Remuneration of General Practitioners.) The Minister considers that consent ought to be given in cases where there is reasonable justification for so doing. Such justification might exist in the case of a doctor who is starting a new practice, or working up a small one, the doctor who on account of age or ill health is unable to do as much as he has done in the past (when it is necessary that his services should be given), or the rural doctor in a sparsely populated area who cannot attract a large list (though these last cases will normally be covered by an inducement payment). It is possible that in a few areas where the proportion of doctors to the population is at present unusually high, the coming into operation of the National Health Service may result in a drop in doctors' incomes. Consent should therefore also be given in the Minister's view in any case where a doctor's income can be shown to have dropped substantially as a result of the new service involving an element of hardship.'

It is implicit in the Minister's statement and in the profession's agreement with him on this matter that the individual applicant should prove reasonable justification for basic salary. Bearing in mind that any additional payment comes from his colleagues, it is reasonable that his colleagues should not be called upon for such additional payment unless a practitioner can justify its need.

## NATIONAL HEALTH SERVICE (SUPERANNUATION) REGULATIONS DISTRICT MEDICAL OFFICERS

A number of practitioners previously holding appointments as district medical officers or medical officers of public assistance institutions will have entered the National Health Service as general practitioners on the lists of executive councils on the appointed day (July 5, 1948). Practitioners in this category who were subject to the Local Government Superannuation Scheme or to a Local Act Superannuation Scheme may reckon any previous service which they were entitled to reckon under those schemes provided they (1) notify the new employing authority of their previous service in writing within three months after entering the Health Service and (2) repay any sums paid to them by way of return of superannuation contributions. The practitioners concerned who entered the new Service on July 5 are reminded that the last day for notifying the new employing authority—in most cases the local executive council—is Oct 4, 1948.

## Correspondence

### Professional Secrecy

SIR,—One of the disturbing features of modern health services sponsored by public authorities in England and Ireland is the determination with which officialdom insists on the destruction of professional secrecy. This must inevitably lead to the corruption of the art of medicine and its members. Man and woman own their own bodies and are given the power of disposing of them by nature and according to its laws. The State cannot nationalize this ownership. One of the primordial rights of man is the right of privacy of his body. As all rights arise from duties, this duty of privacy of our bodies is a duty to the race and is a deeply ingrained instinct of sense and reason. For this reason humans instinctively require privacy in relation to the doctor. The patient is compelled to reveal his or her body to the doctor in order to secure urgently needed help, and hence the doctor, and only the doctor in attendance, obtains this confidence for the exclusive purpose of giving this help. This means that he is in honour bound to use it for no other purpose. He is only released from this obligation when the keeping of the professional secret will minister to crime or fraud, or when required by the patient.

The medical profession for centuries has maintained this as a basic principle of honour and of moral duty even under oath. What is happening to the profession that it should witness such a fall? We see leading and humble doctors repudiating this duty and the right of the patient.

In England we are to have committees prying into the secrets of the private lives of the bodies of man and wife. Northern Ireland says that the committee will be composed of medical practitioners, and Eire says 'persons authorized by the Minister or local authority.'

It is obvious that a doctor who agrees to any non medical committee seeing medical records has forgotten the very basis of professional life. In the case of a medical committee or medical inspectors of the Ministry demanding to see records we are in a more strange position. If it is wrong for a doctor in attendance on a patient to tell anyone except the doctor whose help he requires in assisting the patient, then it is doubly wrong for a doctor to pry into the secrets of another doctor's patients. In the case of men whose names are on the Medical Register and who are Government officials we must realize they are agents of the State and only incidentally are they

doctors. They are not helping the patient and hence have no right into the case and the ordinary professional code should command them to keep out. They have not the excuse of the layman, who might not be expected to realize the meaning of the tradition.

Recently in Eire a doctor was found guilty of conduct infamous in a professional respect for demanding information from another doctor concerning a patient of the latter. It therefore appears that our doctors on committees on records and Government inspectors can throw the professional code overboard and the General Medical Council does nothing while at the same time it will destroy other doctors for doing the same as the doctors on these committees and in Government offices.

The full effects of this departure will take many years to be seen. We will gradually develop two classes of doctors—those who keep the secret and those who do not. The self-respecting citizen will go to the first and our whole public authority medical services will fall into disrepute. This can only be avoided if the doctors and public authorities will combine to restore the moral foundations of the profession by respecting the sacred rights to secrecy of the sick person—I am, etc.

Limerick Eire

JAMES MCPOLIN

### Association of Whole-time Salaried Specialists

SIR—Further to the notice which was published in the *British Medical Journal* (July 17 p 183) the members of the Association of Whole-time Salaried Specialists, formerly the Association of Municipal Specialists feel that much was done in the past by the old Association to secure them adequate representation on important medico-political committees, and valuable advice has been given on salaries, legal problems, etc. This work will be carried on by the new Association and it is thought that its four principal objects will be of interest to your readers—namely

- (1) To improve the practice of medicine in all its branches
- (2) To improve the status and promote the general interest of whole-time salaried specialists
- (3) To provide opportunity for discussion on matters of professional interest and policy
- (4) To promote good relations between all specialists

All whole-time salaried specialists are eligible for membership and I shall be pleased to supply further information on request. Letters should be addressed to the Association's office at 45, Lincoln's Inn Fields London, WC2 (Telephone HOLborn 3474)—I am, etc.,

RUFUS C. THOMAS,  
Honorary Secretary

### Capitation Fee

SIR—The letters of Drs Humphrey Foxell (*Supplement* Aug 21 p 90) and C J Penny (p 91) deserve very close consideration by the Negotiating Committee and the Minister of Health, particularly if it be true that the Minister is likely to cut the capitation fee to some 15s or thereabouts.

With reference to Paragraph 1 in Dr Foxell's letter it is suggested that Dr A with some 2,000 one-time private patients to whom he devoted much care and skilled attention as compared to his colleague Dr B, who had some 4,000 mainly panel and dependant (private) patients to whom he devoted equally skilled but, because hurried less careful attention, were both equally well off financially but are now in a curious position. Dr A will either have to increase his clientele and lower his standard or Dr B will have to decrease his clientele and raise his standard of attention to his patients. This general levelling is what the Minister would like to see although his avowed intention is to raise the standard all over.

It would appear that there is only one way to make a raising of the standard effective and that is to pay each doctor on a much higher scale for the first thousand patients on his list and a very much lower scale on the third and fourth thousands. For example assuming that the overall capitation would work out at 17s 6d per head I would suggest that the scale be as follows: first thousand 20s, second thousand, 17s 6d, third thousand 15s, fourth thousand, 12s 6d. The doctor with 4,000 patients would only receive an overall capitation fee of 16s 3d but this or even a lesser amount, would have to be accepted since so many practitioners would come under the scale for the first and second thousands only. In the case of partnerships a still further grading down might be necessary on

the third, fourth and fifth thousands on the combined totals of their lists. It is difficult to see what sound arguments there can be against such a graduation of scale of payment.

One other point. What has happened to the promised £7 7s and £5 5s payment for maternity services? The London Executive Committee, through the London County Council has stated the fee to be £4 14s 6d in all cases and £2 12s 6d if only one attendance is given—i.e., at the birth—the other £2 2s being for antenatal care all visits during the puerperium and the post-natal examination. Since £2 12s 6d is also given for one attendance at a PPH or an abortion, it would appear that the doctor is not encouraged to take any great interest in antenatal or post-natal care. This is very contrary to what is the rule in good private obstetric practice: there antenatal care being considered so important that, if effectively carried out there has been little or no need for active assistance (although in attendance in case he be needed) by the doctor at the birth in an increasingly large proportion of his total confinements.

The Civil Servant in Whitehall is a very capable man in making regulations complete and tidy and all embracing but he does seem to be sadly divorced from realities. We used to meet the same type in high position in the Army, where rule of thumb often prevailed over plain practical common sense, leaving one with a sense of impotent frustration. "Be wise my son, and let who will be clever" might be a sound axiom for our present bureaucrats to take to heart—I am, etc.

London SW 2

J MELVIN

### Simpler Administration

SIR—I carry four certificate books, two prescription books and a map showing the complicated boundaries of Middlesex and London. Other doctors may have as many as four county executives to deal with. In calculating earnings and pensions mistakes are more likely to occur when two or more councils are at work. Surely it would be simpler, more economical and less open to error for a doctor to be dealt with only by the authorities of the county in which he dwells, giving him one code number, one account, one prescription book and set of certificates—I am, etc.,

London NW 11

## Association Notices

### Diary of Central Meetings

14 Thurs Journal Committee, 2 p.m.

### Branch and Division Meetings to be Held

AYRSHIRE DIVISION—At Ayrshire Central Hospital Irvine Sunday, Oct 3, 7 p.m., Clinical meeting.

BOURNMOUTH DIVISION—At Royal Victoria and West Hanley Hospital, Bournemouth, Bournemouth, Friday, Oct 8 8.15 p.m. Ordinary meeting and special meeting. Agenda: Report of Representatives to Annual Representative Meeting, 1948. Address by Mr R W Raven. Recent Advances in the Surgical Treatment of Cancer.

LEWISHAM DIVISION—At St John's Hospital, Lewisham, SE Friday, Oct 8, 8.30 p.m. Address by Dr P F Ashton. The Treatment of Minor Rheumatic Ailments.

PORTSMOUTH DIVISION—At Kimbell's Corner House Restaurant Commercial Road Portsmouth Tuesday, Oct 5 8 for 8.30 p.m. Dinner meeting. Address by Mr Frederek Ridley. Contact Lenses.

WESTMINSTER AND HOLBORN DIVISION—At Royal Cancer Hospital Medical School 24 Onslow Gardens, Fulham SW Wednesday, Oct 6 8.30 p.m. Lord Horder. General Approach to the Cancer Problem.

### TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade or other organization.

*Metropolitan Borough Councils*—Fulham, Hackney, Pop

*Non-County Borough Councils*—Dartford Radcliffe (to future appointments), WallSEND

*Urban District Councils*—Denton, DroylSDen, Houghton Spring Huyton-with-Roby, Portslade, Redditch (restricted new appointments) Tyldesley

LONDON SATURDAY OCTOBER 9 1948

## SURGERY OF CONGENITAL HEART DISEASE\*

BY

MAURICE CAMPBELL, MD, FRCP

*Physician Guy's Hospital and National Hospital for Diseases of the Heart*

The surgical treatment of some forms of congenital heart disease has raised many fresh questions of diagnosis and prognosis for the physician, as well as many problems for the surgeon. I shall deal with only some aspects of these

### Patent Ductus Arteriosus

The diagnosis of patent ductus is generally easy in the presence of the long continuous murmur through systole and diastole. The diagnosis may sometimes be made without these, but only after much experience, dilatation of the pulmonary artery, an increased pulse pressure at rest or after exercise, and a harsh systolic murmur will then be the main indications. In ordinary cases the two former are some guide to the amount of blood passing through the ductus. An adequate knowledge of the prognosis without operation is lacking, and we do not know with certainty whether the relative absence of cases over 40 is due to many deaths or to many cases closing spontaneously. A recent follow-up by Benn (1947) shows how few complications and symptoms arose in children over an eight-year period when the diagnosis was made at a routine school medical examination.

The first case of patent ductus arteriosus was ligated in 1826, Gross, and experience has now been acquired in many centres. If there is no other congenital lesion the operation is entirely curative and the patient should be quite fit after it, the risks of infective endocarditis and of early heart failure should be entirely avoided. Surgical opinion is still divided between the question of ligation of the ductus and of resection with double ligation. The former is easier and should be the routine procedure, except in special circumstances, in spite of a small risk of necrosis.

The outlook is naturally different in the infected and non-infected cases. In the latter the mortality in skilled hands is low, perhaps 5%. In the infected cases the mortality is naturally higher, but even before the introduction of penicillin it was shown that surgical treatment was often an effective cure for such cases, the introduction of penicillin has made the risks in such cases much less. Many authorities recommend that in all cases in which the ductus has not closed spontaneously by the age of 7 an operation should be performed. Others, and I include myself among them, would limit it to those cases in which there is some defect of the heart, some striking fullness of the pulmonary artery, or some significant symptom.

The slightest degree of cyanosis or of right ventricular hypertrophy electrocardiographically should prevent a decision to operate, as the patent ductus may be an important part of the circulation. After the age of 20 the

risks of operation are rather greater, but the chance of successful operation should not be refused if the symptoms appear to be troublesome or progressive. If infective endocarditis is present when the patient is first seen it should be arrested with penicillin treatment, and generally operation should be advised later because of the risk of recurrence.

### Coarctation of the Aorta

The diagnosis of coarctation of the aorta will continue to be missed if a collateral circulation is always expected to be self-evident. The femoral pulse should be felt for and the blood pressure taken in the legs in every case in which high blood pressure, basal systolic or diastolic murmurs, or undue pulsation in the neck is present without an obvious cause. A high pressure in the arms and a low poor femoral pulse or the demonstration of a collateral circulation are pathognomonic of coarctation of the aorta. They are more important than notching of the ribs, not only because x-ray films are not always available but because the signs are present at an earlier age.

The collateral circulation can be more easily demonstrated or made more obvious if the patient stoops forward with his arms hanging down vertically while his back is examined in a good light. This is because the greatly dilated subclavian artery is compressed between the clavicle and the first rib and bending forward opens up this space and so releases the pressure on the subclavian artery.

We know more about the prognosis of coarctation. The average age at death is about 30. Two groups can be distinguished: those with symptoms before adult life, who will probably not live beyond 30, and those in whom the lesion is found by chance in adult life, the outlook being very much better. Most patients die from cardiovascular causes—heart failure, endocarditis, or a ruptured aorta—but one in ten may die from the rupture of a congenital cerebral aneurysm.

In October, 1944, Crafoord successfully resected a case of coarctation with an end-to-end suture of the aorta. In his first series (up to July, 1947) the results were entirely satisfactory in 20 and two patients died; in three patients after a thoracotomy no operation was possible and two of these died. In these 20 patients the blood pressure in the upper part of the body fell to or near to normal, the pressure in the legs rose, and the circulation was greatly improved as shown by oscillometric records. Some parts of the visible collateral circulation disappeared quickly and the patients felt better and were able to do much more.

It may be some time before the general operative risk can be assessed, but Crafoord's mortality of 16% and experience at other centres would justify a reasonable risk in those patients in whom the outlook seems unfavourable, considering the greatly improved expectation of life. The

only sense in which the operation is not a complete cure is that bicuspid aortic valve or congenital cerebral aneurysms may be present. A fall of blood pressure to normal will greatly reduce the risks from the latter, but we cannot be sure that it will remove it entirely.

Atheroma develops in the aorta at a younger age in patients with coarctation, this adds to the risk of operation after the age of 20 or 25 years and is one of the reasons favouring early operation.

### Cyanotic Congenital Heart Disease

Here the problems are much more difficult both for the physician and for the surgeon. Until recent years nothing could be done for these patients and they lingered on with increasing incapacity, some reaching a very limited adult life, but many died in infancy and more during childhood. Two centuries ago the association of cyanosis with pulmonary stenosis and with ventricular septal defect was recognized and there has been much discussion about their relative importance. It was Dr. Taussig's recognition of the inadequate flow of blood to the lungs as the fundamental cause of the disability that led to the idea of a successful operation, although the right-to-left shunt of venous blood actually produced the cyanosis.

### Diagnosis

In early infancy many malformations of the heart may be responsible for gross cyanosis, but the more serious are not long compatible with life. As the children get older fewer forms of congenital disease are found with any frequency and this makes an attempt at diagnosis possible. Cyanosis from birth generally represents a right-to-left shunt either through a ventricular septal defect or because there is an overriding aorta that takes the blood from the right ventricle or, in an extreme case, where the aorta, being transposed, takes all its blood from the right ventricle.

The fundamental requisite for success of the Blalock-Taussig operation is that the cyanosis and disability should be mainly due to an inadequate blood-flow to the lungs, and when pulmonary stenosis is added to these other findings, as it is in Fallot's tetralogy, the operation is most certain to be successful.

Fallot's tetralogy consists of pulmonary stenosis (which may be valvular or infundibular), ventricular septal defect, an overriding aorta (that has often been called dextroposition), and right ventricular hypertrophy. The condition was very fully and accurately described by Peacock in 1858—20 years before Fallot's paper—and had been recognized earlier than this. These three abnormalities occurring together without pulmonary stenosis are known as Eisenmenger's complex. Pulmonary stenosis may also occur alone, but then there is generally no cyanosis from birth. Its later development probably depends on a septal defect which may be small and no more than a foramen ovale where the valve preventing a flow from left to right is overcome by the increased pressure on the right side so that there is a flow from right to left.

The majority of children with cyanosis from birth and clubbing of the fingers have Fallot's tetralogy, and often where the x-ray picture is characteristic this can be diagnosed with confidence. The main features are persistent cyanosis from infancy, with polycythaemia, clubbing of the fingers, and severe disability on walking. On radio-scopy the heart which may be sabot-shaped in half the cases, shows little enlargement generally but some enlargement of the right ventricle. There is no undue prominence of the pulmonary arc and no visible pulsation in the pulmonary branches. Most of them have a systolic murmur in the pulmonary area, often with a slight thrill. The

pulmonary second sound is never much increased and is often diminished. A diastolic murmur indicates some complication. Most of them have right ventricular preponderance in the electrocardiogram, with a large pointed P II. All are of normal mental development unless there are other causes for abnormality, most are underweight but of normal height. Squatting is noted in four-fifths of the patients, and panting after exertion is nearly as characteristic.

Although the diagnosis may be easy there are difficult borderline cases. The critical decision clinically is whether the pulmonary blood-flow as seen on radio-scopy is diminished or not. Often it is easy to decide that this is diminished, as there is a hollow pulmonary bay and the lung fields look clear. In other cases (most familiar in the adult picture of auricular septal defect) it is obvious that the pulmonary arteries are dilated with increased pulsation. Difficulties are caused by the cases in which beyond the pulmonary stenosis there is some dilatation of the pulmonary arteries and in which a good collateral circulation produces increased density in the lung fields.

Fallot's tetralogy is the commonest finding among children who are obviously blue, but as one sees an increasing proportion of less cyanosed children there are more with other lesions and with a radiological picture similar to adult auricular septal defect. This defect alone cannot be the cause, because the pressure being higher on the left than on the right, there is no cyanosis except perhaps terminally. Whether there are exceptions to this statement is one of the problems that remain to be solved, but more likely there is also transposition of the main vessels as well (Taussig, 1947). In Eisenmenger's complex also the pressure in the pulmonary artery is high, the blood-flow to the lungs is unimpeded, and operation will not help. In difficult cases great help may be obtained by the circulation times, cardiac catheterization, and by angiocardiology.

If the oxygen content of the blood in the right auricle is considerably higher than that in the superior vena cava there must be an auricular septal defect with a left-to-right shunt (a right-to-left shunt would not of course show by this method, though a catheter might pass through the septal defect). If the pressure is raised in the right ventricle and suddenly falls greatly as the catheter passes into the pulmonary artery, there is pulmonary stenosis, but it is not always easy to get the catheter into the pulmonary artery. A high pressure in the pulmonary artery often indicates Eisenmenger's complex, though it may occur in other conditions. A very high pressure on the right side, approximating to that in the aorta, suggests a septal defect with an overriding aorta and free communication between the two. Detailed calculations may often be made about the size of the blood-flow through the different circuits and shunts, while these are of great interest they are hardly reliable enough to be conclusive.

In angiocardiology quick filling of the left ventricle and of the aorta and its branches indicates a septal defect with a right-to-left shunt. Slow filling of the pulmonary arteries after the right ventricle has been visualized indicates pulmonary stenosis. In many cases other interesting details are observed, though considerable skill and experience is needed in the interpretation of the pictures. From such a simple investigation as the circulation times one may be certain of the presence of a large right-to-left shunt if the arm-tongue time is the same as or shorter than the arm-lung time.

### Prognosis

There are few follow-ups of these children to give an accurate prognosis. If one may take the age incidence of a recent series as an indication, it is very unfavourable. In my first 137 patients (77 males and 60 females) with cyanotic

congenital heart disease there were almost equal numbers in each year up to 7, three-fifths of this number in each year from 8 to 11, and one-fifth of this number in each year from 12 to 22, after which there were only scattered cases. The figures suggest that those surviving infancy have no great risks until they reach the age of 7, though clinical experience hardly bears this out. After 7 the chances of surviving become less, and increasingly so after the age of 12.

If these figures can be taken as giving a true cross-section they mean that only one patient in ten reaches the age of 24 and only two in ten the age of 12. Many parents have been told that their children will not live to 7 or to 14 or to 21, and there seems some rough truth in these three round numbers as representing periods of increasing danger beyond which survival becomes less likely. During the last few months there have been some deaths after operation, but there have been many more among the other patients I have seen. These considerations seem ample justification for advising operation in spite of the relatively high mortality. The incapacity of many of these cases is hardly realized. A few may lead a reasonable but very quiet life, but if they are old enough to express their views they are generally the greatest enthusiasts for operation, even when the risks are put before them. Many, however, exist rather than live and are a handicap to their parents as well as to themselves, especially when they begin to realize what other children are able to do.

#### Operative Treatment

Following Taussig's suggestion about the importance of overcoming pulmonary stenosis, Blalock's experimental work on animals convinced him that a subclavian-pulmonary anastomosis was a feasible method, and in October, 1944, Blalock and Taussig introduced their operation for the relief of the inadequate blood-flow to the lungs in Fallot's tetralogy and related lesions.

The operation is essentially an anastomosis between a systemic artery and the pulmonary artery, most commonly an end-to-side subclavian-pulmonary anastomosis, though under special circumstances the innominate or carotid artery may be used or the anastomosis may be end-to-end. In one-quarter of these cases the aortic arch will be right-sided instead of curving back as usual to the left and this will of course change the position of the innominate artery. The operation should be performed on the side opposite to the aortic arch because this gives a greater choice of systemic vessels that can be used and the subclavian artery can generally be turned down to the pulmonary artery with a less acute angle.

In infants the small size of the vessels produces a surgical problem of the greatest difficulty, and the operation is much more dangerous and sometimes less lasting in its good effect because the anastomosis is too small as the child grows larger. For this reason the operation should never be performed before the age of 3, except as a life-saving emergency, and generally not till 5. From 5 to 10 is perhaps the ideal age, but there seem no special difficulties in older children, though the difficulties and risks are greater in those over 20—a group that should not trouble our successors, as suitable cases should have been operated on earlier. The direct division of the stenosed pulmonary valve by Brock (1948) has opened up fresh possibilities. The late results of this and the indications for it remain to be worked out.

#### Results of Operation

The operation is not of course curative in the same way as in the other two groups because the underlying abnormality remains, but the improvement may be so great that the child appears normal to the parents. The immediate

upset caused by the operation is less than might be expected and intravenous fluid is often not required, when it is used only small amounts are needed. Many have a pleural effusion that often needs aspiration, but generally only once, other complications are not common. Of the first 38 cases operated on at Guy's Hospital 6 died, 7 could not have an anastomosis done or did not benefit much, and the remaining 25 were enormously improved almost at once and this has been maintained.

The immediate results of the operation are excellent, and the improvement seems to be maintained over the period of two to three years for which it has been possible to follow up Blalock's patients. The colour becomes nearly normal except sometimes for slight cyanosis on a cold day or after vigorous exercise, and the patients' capacity is greatly improved so that they can walk some miles and get about normally all day. The polycythaemia disappears quickly, the clubbing of the fingers more slowly. The arm on the side of the divided subclavian artery gives no trouble.

The heart enlarges a little as might be expected from the increased work, but generally only slightly. Sometimes at the beginning the increase during the first few weeks made me feel that any such progressive increase would soon end in disaster, but I have seen no cases in which the increase has continued after the first month or two, and I understand that in the longer American experience this is a rare occurrence, though relapses in those operated on too young and a few instances of congestive heart failure have been seen.

## LARGE-INTESTINE COLIC DUE TO SYMPATHETIC DEPRIVATION

### A NEW CLINICAL SYNDROME

BY

SIR HENEAGE OGILVIE, KBE, MCh, FRCS

Surgeon to Guy's Hospital

The subtitle of this note is intentionally provocative. Two cases are described, presenting essentially similar features. In each case the symptoms so strongly suggested obstruction of the distal colon by a carcinoma that laparotomy was eventually undertaken in spite of normal findings in a barium enema. In each case the operation disclosed a normal colon and extensive and entirely unsuspected malignant disease involving the region of the crura of the diaphragm and the coeliac axis and semilunar ganglia.

Whether such a syndrome has been described before I am unaware, but I have not encountered it apart from these two cases, nor have any of my friends whom I have consulted on the subject, and a search of the journals over the last ten years and of the literature of hypertension has failed to reveal similar observations.

#### Case 1

In 1944 a physician aged about 66, on the staff of an E.M.S. hospital, began to lose weight, and complained of increasing constipation. He was found to be diabetic, and was treated with diet and insulin. The diabetes was controlled, but the constipation persisted, and he began to have colicky pains in the hypogastrium. On several occasions waves of peristalsis,

parently in the pelvic colon were seen during attacks of colic. A barium meal, and later a barium enema failed to show any abnormality. The symptoms increased in severity, and after two months the barium enema was repeated. It revealed a dilated and apparently atonic colon but no localized deformity or obstruction. The attacks of colic continued and he lost weight progressively, so that in spite of the absence of any positive findings a laparotomy was advised.

At operation free fluid was found in the abdomen. The colon was normal throughout. There was a malignant nodule in the peritoneum behind the umbilicus, and a malignant mass on the left crus of the diaphragm which might have originated in the adrenal, the tail of the pancreas or the upper pole of the left kidney. The infiltration spread across the region of the aortic opening and there were metastases in the liver. The nodule in the peritoneum was excised and sent for section, and later was reported to be typical of a secondary deposit of carcinoma of the pancreas.

The patient died three months after operation. No necropsy was performed.

### Case 2

In February 1948 a solicitor aged 58, who had been perfectly well all his life except for an operation for appendicitis with general peritonitis at the age of 17 and attacks of dysentery during the first world war began to suffer from attacks of generalized colicky abdominal pain accompanied by constipation and relieved by passing wind. Between the attacks which came on several times a day, he felt well.

On April 1 he was seen by Dr Geoffrey Evans, who has kindly placed at my disposal the notes he made at the time. The patient told him that the attack had started suddenly six weeks previously with pain in the abdomen, wind, and constipation and he attributed it to worry and an injudicious feast of whisky and gooseberries. Up to this time his digestion had been good and his bowels had acted regularly without laxatives. After the pain started he took a series of aperients and purgatives, which either failed to act or produced a loose motion only. A provisional diagnosis of intestinal obstruction was made, and the patient was referred to Dr Norman Henderson for a barium enema. Some early diverticulosis of the left colon was reported but no filling defect. The differential diagnosis of enterospasm was considered, but was rejected because of the obvious distension of the lower part of the abdomen and because bowel function had been normal up to the onset of the illness. There had been some weight loss (about a stone 6.35 kg) but this might have been explained by reduced food intake and disturbed sleep due to the pain.

He returned to his home in the country, but the attacks continued and one which occurred a week later was so severe that it seemed to indicate a commencing obstruction. He was admitted at once to a nursing home for observation, when I saw him for the first time. He was then having bouts of pain three or four times a day. Each started suddenly, with violent hypogastric colicky pain, which made him writhe about and grip the bedclothes. His pulse rose to 100 but his temperature was unaltered. He did not vomit. During the attack he was tender in the left iliac fossa and what appeared to be a distended loop of colon could be felt to the right of the tender spot. The attack lasted from half to one hour. When it was over he was happy, he had no pain, and his abdomen was soft and free from tenderness.

The differential diagnosis between enterospasm and obstruction was again discussed with Dr Geoffrey Evans who remained in charge of the case. The patient was of the highly strung type, in whom enterospasm is to be expected. On the other hand lower abdominal distension, which is not seen in enterospasm, was an obvious feature, and he had never experienced similar pain previously. Sigmoidoscopy and analysis of the faeces showed no abnormality. No formed stool was passed in spite of a variety of daily enemata atropine by injection, magnesium and belladonna and paraffin oil  $\frac{1}{2}$  oz (57 ml) daily. After a week I wrote to his doctor. I feel we shall be driven to laparotomy but I feel still more certain that we shall find nothing visibly or palpably wrong. However, he cannot go home as he is and we will therefore have to operate if we cannot cure him in some other way. The attacks got worse and more frequent.

At operation ten days after his admission to the home no free fluid was found, and the pelvic colon appeared normal except for a temporary ring of spasm—an unusual sight under general anaesthesia. In the subdiaphragmatic region masses of malignant tissue were encountered. All the upper aortic glands, those round the coeliac axis and those in the lesser omentum were large and hard, there were large hard nodules in both lobes of the liver, and the falciform ligament and the peritoneum on each side of it were infiltrated. No indication of the site of the primary tumour could be discovered.

The falciform ligament was removed for section and reported on as follows. The specimen shows the remains of a gland containing considerable secondary deposits of a carcinoma composed of compact groups of small elongated cells with darkly staining nuclei and some abnormal mitoses and without alveolar arrangement. The general appearance somewhat suggests origin in a bronchial carcinoma, possibly of oat cell type, but the character is very difficult to define more clearly. Another pathologist reported "I think this is clearly a secondary deposit in connective tissue of an adenocarcinoma, with a tendency to spheroidal change. It would do extraordinarily well for a bronchial neoplasm." A third pathologist considered that the appearance suggested a tumour arising in the adrenal.

The patient died two weeks later. No necropsy was performed.

### Discussion

The symptoms and signs of colonic obstruction in these two cases, occurring in the absence of any organic disease of the colon itself, can be explained in three ways: (1) That the tumour stimulated the parasympathetic supply to the colon. (2) That the tumour cells produced some substance stimulating peristalsis. (3) That the subdiaphragmatic growth had interrupted the sympathetic supply to the large intestine, so that the parasympathetic innervation, which in the distal colon comes from the second and third sacral nerves, was allowed to act unopposed. Of these three explanations the third alone is probable. Infiltration of a motor-nerve bundle should not produce overaction of the muscles it supplies, nor should any kind of mechanical stimulation of nerve fibres in their courses produce repeated overaction. Further, in these instances the neurones of the caudal sympathetic system, which supply the section of the bowel involved, were far removed from any abnormal environment. Tumours secreting parasympatheticomimetic substances are, so far as I know, unknown, in any case, the response in these two patients was a local and not a general parasympathetic one.

That the removal of the sympathetic innervation to the colon should lead to excessive and possibly incoordinated contraction of the muscle coats is not improbable. Bilateral ablation of the lumbar sympathetic chain has in a number of instances led to considerable and permanent diminution in the diameter of the bowel in congenital megacolon. Temporary paralysis of the sympathetic system by a spinal analgesic leads to contraction of that part of the alimentary canal supplied by the vagi. Injection of drugs that act on the neuromuscular junction of the parasympathetic system—prostigmin and acetylcholine—causes contraction, often excessive and painful, of the muscular coats of the small and large intestines.

In the two cases under discussion the malignant infiltration surrounded, and may well have put out of action or even destroyed, the splanchnic nerves, the semilunar ganglia, and the coeliac plexus. The vagi passed through the same invaded area, and were equally liable to interruption—a fact that fits in with the observation that only that part of the bowel supplied by the caudal parasympathetic system gave clinical evidence of the overaction. There is no unanimity among anatomists about where the watershed between the vagal and the sacral supply lies, but it is usually presumed to correspond roughly to the junction between

the parts of the colon developed from the midgut and hindgut loops—that is, about the distal fourth of the transverse colon

The most cogent objection to the view that these two cases represent parasympathetic overaction due to sympathetic deprivation is that in each case the contractions were painful. Pain fibres from the small and large intestines reach the cord, so far as we know, by way of the splanchnic nerves. Bentley and Smithwick (1940) showed that the appreciation of pain in the small intestine is abolished after bilateral splanchnicectomy, and Rav and Neill (1947) showed the same in the large intestine. The operation of splanchnicectomy has not, so far as I know, ever been followed by muscular overaction in the bowel.

We thus have two objections to the explanation of sympathetic deprivation put forward to account for the clinical syndrome here discussed—that surgical interruption of the sympathetic nerves at the same site does not produce this effect, and that it does abolish pain, which in these cases was not abolished.

Three suggestions may be made to account for this discrepancy. First, that the interruption of nerve fibres by malignant infiltration may be 'selective', picking out the motor fibres before the sensory ones. We know that in pressure lesions (tourniquet paralysis and obstetric paralysis) and traction lesions (brachial plexus injuries) involving nerve trunks motor power may be lost with little or no sensory disturbance. In this particular instance the motor fibres (at any rate, the post-ganglionic ones in the plexus) are non-medullated, while the sensory ones are medullated, and this chemical and histological difference may be accompanied by a differential resistance to infiltration.

Secondly, that the sensory and motor fibres may not run together in all individuals as they do in the majority. One fact that is appearing as the result of the great increase in operations on the sympathetic system is the astonishing and unpredictable course of the sympathetic pathways, particularly at the thoraco-abdominal junction. Boyd (1948) has shown that it is impossible, by the most complete ablation of all known sympathetic nerves and ganglia, to produce functional denervation of the sweat glands in the D/2 and L1 areas.

Thirdly, that painful sensations, blocked in their normal pathways, may find others. The motor cortex orders movements, and when the muscles or nerves that normally subserve those movements are destroyed will often accomplish the same movements by some other mechanism. The sensory cortex awaits messages, and if the orthodox routes are out of action will often receive them by underground channels. The pain of angina pectoris ceases after bilateral resection of the first four thoracic ganglia, but it comes back eventually. The pain of hip disease is cured for a time by antero-lateral cord section, but the relief is only temporary.

I should like to express my gratitude to Professor F. H. Bentley, Professor Michael Boyd, Sir Stanford Cade, Dr Geoffrey Evans, Professor F. A. Knott, Professor G. A. G. Mitchell, Professor A. H. T. Robb Smith, Sir Charles Symonds, and Mr A. G. M. Weddell (the order is alphabetical) with whom I have discussed these cases.

## SOME CAUSES OF SLIGHT CARDIAC ENLARGEMENT

BY

RONALD HARTLEY, M.R.C.P.

Assistant Physician, Miller General Hospital and Dreadnought Hospital for Seamen London

In routine radiological examination cardiac enlargement without physical signs of valvular disease or hypertension is sometimes seen. Among 2,500 recruits examined this problem arose in 25 men, and an attempt has been made to find the cause of the enlargement in 16 of these who were followed up and re-examined three to six years later. Two further cases seen after the original series (Parkinson and Hartley, 1946) are added.

#### Method

Opinions differ as to the best method of determining whether true enlargement is present. Hodges and Eyster (1926), Ungerleider and Gubner (1942), and Sherman and Ducey (1944) prefer exact cardiac mensuration. On the other hand, Bedford and Treadgold (1931) say that screen examination is a more reliable means of recognizing heart disease than is actual measurement by orthodiagram. Comeau and White (1942) find prediction tables the best approach to the problem, but both agree that the important factor in estimating heart size is the impression gained by a reliable and experienced radiologist. Parkinson (1936) thought that cardiometry was too complicated for routine clinical use, and that as sound an opinion could be given from screen examination without measurements.

In the type of case discussed measurements are of little use, as they usually fall between the minimum and maximum limits of normal. Careful radioscopy in the three routine positions by more than one experienced observer is more accurate in arriving at a conclusion, and this was the method here adopted. In every case the second examination was made without reference to the previous report. Table I shows the possible causes of radiological enlargement without physical signs of valvular disease or hypertension.

TABLE I—Showing Possible Causes of Radiological Cardiac Enlargement in the Absence of Physical Signs of Valvular Disease or Hypertension

- 1 Physiological—Childhood, athleticism, bradycardia, and pregnancy
  - 2 Apparent—Scoliosis, depressed sternum, and raised diaphragm
  - 3 Familial cardiomegaly and congenital idiopathic hypertrophy. Friedreich's ataxia
  - 4 Organic heart disease—V.D.H. before the development of murmurs, congenital heart disease, repeated coronary thrombosis, cardiac aneurysm, and antecedent hypertension
  - 5 Abnormal rhythm—Complete heart-block, paroxysmal tachycardia with failure, auricular fibrillation, and bundle-branch block
  - 6 Arteriovenous aneurysms and Paget's disease of bone
  - 7 Metabolic endocrine and blood disease—Anaemia, thyrotoxicosis, myxoedema, and beriberi
- Other rarer causes are anomalous coronary arteries, Fiedler's myocarditis, amyloid disease, Gaucher's disease, Von Gierke's disease and acromegaly.

Among the 18 cases were examples falling into the first four groups only. Table II shows the final conclusion reached.

TABLE II—Showing the Final Diagnosis made in 18 Cases of Cardiac Enlargement in the Absence of Physical Signs of Valvular Disease or Hypertension

Case No	Final Diagnosis

18	Probable aortic incompetence (rheumatic)

### Apparent Cardiac Enlargement

It is well known that scoliosis of minor degree, depressed sternum, or a raised diaphragm may cause apparent radiological enlargement. Although scoliosis or depressed sternum was recognized as a contributory cause in four men at the first examination, the heart in all was still considered to be larger than normal. Reconsideration at the second examination showed that all four had, in addition, a bradycardia.

**Case 1—Aged 40** First examination October, 1941—B P 130/85. The mitral first sound was loud and there was a moderate apical systolic murmur. Radiologically the left ventricle was suspected of being too large. Second examination May, 1947—Pulse rate 60. There was a minor degree of depressed sternum. The apical first sound was loud and a moderate apical systolic murmur was present. *Diagnosis* the heart was now considered to be within normal limits in view of the bradycardia and minor depression of the sternum.

**Case 2—Aged 39** First examination, July, 1941—B P 150/85. Apical and pulmonary short but loud systolic murmurs. Electrocardiogram R<sub>1</sub> small and slurred, T diphasic. Full sized heart on radiology. Second examination May, 1947—Slight depression of the sternum. Short soft apical and pulmonary systolic murmurs. Pulse 60. Electrocardiogram unchanged. Radiology full sized heart. Slight displacement by scoliosis. *Diagnosis* bradycardia and scoliosis.

(Note—A diphasic T<sub>2</sub> was found among healthy young aircrew in the 1939–45 war (Stewart and Manning, 1944, Wood *et al* 1941).)

**Case 3—Aged 18** First examination February 1943—Positive rheumatic history. B P 120/80. The pulmonary second sound was loud. Radiology showed slight enlargement, and early aortic incompetence was suspected. Second examination April, 1947—Short soft apical systolic murmur. Clear third heart sound. Electrocardiogram normal. Depressed sternum minor degree. Radiology full-sized heart, normal size in both oblique positions. *Diagnosis* bradycardia and depressed sternum cause the appearance of full size.

**Case 4—Aged 20** First examination May, 1943—B P 140/70. Apex beat external to the nipple line and too forcible. Radiology probably slight enlargement, but heart lies to the left. Possibly early aortic incompetence. Second examination March 1947—Apex beat beyond the mid-clavicular line. Short soft apical systolic murmur. Pulse rate 60. Radiology full sized heart. Deep breathing shows it to be of normal size. *Diagnosis* bradycardia and scoliosis cause the appearance of enlargement.

In Cases 5 and 6 a second examination showed scoliosis alone as the cause of the apparent enlargement. These show that a second examination will sometimes correct the previous view that more enlargement is present than can be accounted for by displacement.

**Case 5—Aged 17** First examination February 1944—B P 120/75. Apex beat forcible. Short minimal systolic murmur at apex and on left of sternum. Electrocardiogram

normal. Radiology probably slight enlargement. Second examination April, 1947—Short soft apical systolic murmur. Pulmonary second sound duplicated. Electrocardiogram normal. Full sized heart, but right border is made up of spine. When the scoliosis is corrected by a 5 degree turn to the right the heart is normal in shape and size. *Diagnosis* scoliosis.

**Case 6—Aged 19** First examination September, 1941—Positive history of rheumatic fever. B P 130/80. Apex beat in nipple line. Pulmonary second sound loud. Electrocardiogram normal. Radiology showed probable slight enlargement of the left ventricle, in addition to displacement by scoliosis. Possibly early aortic incompetence. Second examination May, 1947—Apex beat in mid-clavicular line, not forcible. Pulmonary second sound loud. Electrocardiogram normal. *Diagnosis* radiology—scoliosis causes the appearance of enlargement.

### Prominent Aorta

The interest in Cases 7 and 8 lies in the fact that even at the second examination cardiac enlargement was thought to be present. The radioscopic reports in each case are almost identical at both examinations. Yet if heart disease were present some progress over five years might have been expected. At the second examination, knowing the previous findings, it is justifiable to call both hearts normal, but if such a man is seen for the first time serious doubt would still arise. In both cases the ascending aorta was considered at each examination to be too prominent for the age of the patient. It is possible that the vascular pedicle in youth may be wider on occasion than the generally accepted normal.

**Case 7—Aged 19** First examination October, 1941—B P 155/90. Apex beat forcible and displaced. Electrocardiogram normal. Radiology the heart lies slightly to the left. Possibly left ventricular enlargement. Second examination May, 1947—B P 140/70. Apex beat beyond the mid-clavicular line and too forcible. Short pulmonary systolic murmur. Electrocardiogram normal. Radiology showed a full-sized heart, with a vascular pedicle which is wide for his age. Ascending aorta prominent. Left ventricle possibly slightly enlarged. Oblique positions within normal limits. *Diagnosis* probably no heart disease present.

**Case 8—Aged 21** First examination December, 1942—B P 130/80. Apex beat slightly forcible. Long piping apical systolic murmur, heard also in the aortic area. Electrocardiogram left axis deviation. Radiology heart full sized, possibly slight enlargement. Possibly early aortic stenosis. Second examination May, 1947—Apex beat forcible. Short but noticeable apical piping systolic murmur. Electrocardiogram left axis deviation. Radiology heart full sized only. Aorta too prominent for his age. *Diagnosis* this may be a normal heart, but it is not certain even now.

### Right Axis Deviation

Cases 9 and 10 are in many ways similar to Cases 7 and 8, but in these there is right axis deviation in the electrocardiogram. That it is unusual to find this at the age of 20 is true, but among 299 normal students studied by Wood *et al* (1941) it was present in four. Slight widening of the QRS complex often occurs in normal youths, as has been shown by Graybiel *et al* (1944) and by Stewart and Manning (1944). Graybiel *et al* found QRS complexes as long as 0.13 second in normal aviators. Stewart and Manning found prolongation only in leads II and III. Five years after the original examination there was no change in Cases 9 and 10, and the presumption is that they have normal hearts.

**Case 9—Aged 19** First examination November, 1942—B P 130/75. Apical and pulmonary soft systolic murmurs. Electrocardiogram right axis deviation. Radiology slight but definite enlargement of heart. Possibly congenital heart disease. Second examination May 1947—Apex beat beyond the mid-clavicular line. Not forcible. Soft apical systolic

mur Electrocardiogram right axis deviation Radio-  
scopy full sized heart only *Diagnosis* no heart disease  
ent

*Case 10*—Aged 20 *First examination* December 1942 —  
155/90 Apex beat forcible Electrocardiogram right  
deviation with slight widening of the QRS complex, T<sub>1</sub>  
Radioscopy showed slight enlargement of the heart  
and examination April, 1947 —Apex beat beyond the mid-  
clavicular line and forcible Electrocardiogram unchanged  
radioscopy heart appears enlarged, but turning 5 degrees to  
right partially corrects it, and a deep breath then makes  
size almost normal There is some scoliosis, but in spite  
of this there seems to be more enlargement than can be  
accounted for by this and the high diaphragm The size of  
left ventricle raises suspicion, but the electrocardiogram  
shows right axis deviation *Diagnosis* no heart disease  
ent

### Familial Cardiomegaly

William Evans (1948) has recently described cardiomegaly  
occurring as a familial condition, and Case 11 in my  
series proved to be a member of the family described by

*Case 11*—Aged 18 *First examination* June, 1944 —B P  
160 Frequent extrasystoles Apex beat in the sixth space,  
placed and too forcible Radioscopy showed moderate to  
slight enlargement chiefly of the left ventricle Unfortunately  
electrocardiogram was not taken, as at that date work in  
London was carried on under difficulties *Second examination*  
May, 1947 —Auricular fibrillation Electrocardiogram showed  
grossly abnormal QRST complex Radioscopy revealed  
marked enlargement The patient's brother had  
recently died in the London Hospital from heart failure due to  
same condition *Diagnosis* familial cardiomegaly

### Mitral Stenosis

The diagnosis of valvular heart disease is seldom made  
in the absence of the typical murmur In mitral stenosis  
enlargement can appear before a presystolic murmur, and  
sometimes even before an apical systolic murmur is heard  
The latter was seen in five men out of 264 with mitral  
valvular lesions (Parkinson and Hartley, 1946) Case 12  
is thought to be an early example of mitral stenosis,  
though it is not proved

*Case 12*—Aged 19 *First examination* November, 1942 —  
155/80 Apex beat external to the nipple line Short  
systolic murmur in all areas, loudest in the pulmonary area  
Radioscopy showed slight general enlargement Possibly con-  
genital, possibly acquired heart disease *Second examination*  
April, 1947 —Apex beat forcible and in mid-clavicular line  
Apical first sound loud and sudden Pulmonary second sound  
murmured Soft systolic murmur in all areas Electrocardio-  
gram shows sino auricular block with ventricular escape Radio-  
scopy very doubtful enlargement with convex left border, pos-  
sibly due to a combination of scoliosis and low diaphragm In  
right oblique position, with barium in the oesophagus the  
left auricle is probably enlarged and also the pulmonary artery  
In the left oblique position the left auricular enlargement is  
not so convincing *Diagnosis* probably early mitral stenosis

This case raises the question of the diagnosis of early  
mitral stenosis as discussed by Parkinson and Hartley (1946)  
In this is mitral stenosis it is of great interest that such  
deterioration has occurred in a period of nearly five  
years The loud first sound and the probable left auricular  
enlargement make the diagnosis most likely

### Aortic Incompetence (Rheumatic)

On the other hand, the suggestion is not usually made that  
enlargement of aortic incompetence may appear before  
an aortic diastolic murmur is audible under normal con-  
ditions In Cases 13, 14, 15, 16, and 17 of this series a  
definitive diagnosis of possible aortic incompetence (rheuma-

tic) was made at the first examination, based on the radio-  
scopic findings only, although at that time examination  
included a special but futile search for an aortic diastolic  
murmur, in all positions and at different pulse rates On  
second examination in each case a clear aortic diastolic  
murmur was heard

*Case 13*—Aged 41 *First examination* November 1942 —  
History of chorea B P 130/80 Apical first sound split. Pul-  
monary second sound loud Electrocardiogram normal Radio-  
scopy slight to moderate enlargement of the left ventricle  
Probably aortic incompetence *Second examination*, May,  
1947 —Pulse shows auricular fibrillation An aortic diastolic  
murmur is heard Radioscopy general enlargement, with left  
ventricular enlargement and a prominent ascending aorta  
Slight scoliosis with a low diaphragm tended to mask the radio-  
logical findings in this case *Diagnosis* aortic incompetence  
(rheumatic)

*Case 14*—Aged 21 *First examination* July, 1944 —No his-  
tory of rheumatic fever or chorea B P 140/85 Depressed  
sternum and variable apical systolic murmur Radioscopy  
enlargement as well as displacement by the depressed sternum  
*Second examination* May, 1947 —Cup-like depression of the  
sternum Apex beat well beyond the nipple line Aortic  
diastolic murmur on the left of the sternum Electrocardio-  
gram shows right axis deviation Radioscopy considerable  
general enlargement In spite of the depressed sternum the  
heart was thought to be too large The left ventricle was  
slightly enlarged and the pulmonary artery was also slightly  
large In view of the right axis deviation the question was  
raised whether the murmur could indicate pulmonary incom-  
petence the pulmonary artery was not large enough for this  
to be so *Diagnosis* aortic incompetence (rheumatic)

*Case 15*—Aged 18 *First examination* May, 1943 —B P  
140/80 Apex beat forcible, a short apical systolic murmur  
Radioscopy left ventricle slightly enlarged *Second examina-  
tion* April, 1947 —Slight depression of the sternum Apex  
beat forcible and beyond the nipple line Aortic second sound  
loud and an aortic diastolic murmur is present Electrocardio-  
gram left axis deviation Radioscopy moderate general  
enlargement, left ventricle enlarged, and ascending aorta promi-  
nent *Diagnosis* aortic incompetence (rheumatic) It is pos-  
sible that the diastolic murmur was obscured by the loud aortic  
second sound at the original examination

*Case 16*—Aged 18 Seen December 1942 No rheumatic  
history B P 115/70 Short apical systolic murmur only  
Radioscopy probably slight general enlargement Possibly  
aortic incompetence Later, in 1943, a diastolic murmur was  
recorded *Diagnosis* aortic incompetence (rheumatic)

*Case 17*—Aged 18 Seen February, 1943 No rheumatic  
history B P 120/75 Apex beat in nipple line and too forcible  
Radioscopy showed left ventricle enlarged *Diagnosis* Pos-  
sibly aortic incompetence A letter from Sir John Conyngham  
dated July, 1943 when this patient was in the R.A.F., con-  
firmed that there was no diastolic murmur present, although  
one was audible in November, 1943 *Diagnosis* aortic incom-  
petence (rheumatic)

*Case 18*—Aged 19 *First examination* January, 1943 —B P  
140/75 Apical and basal short systolic murmur Radioscopy  
slight general enlargement with undue pulsation of the aorta  
*Second examination* April, 1947 —Apex beat beyond the mid-  
clavicular line and too forcible Third sound well heard Short  
soft pulmonary systolic murmur Electrocardiogram normal  
Radioscopy slight general enlargement left ventricle large, and  
ascending aorta prominent Although repeated auscultation  
failed to show an aortic diastolic murmur, it seems  
probable from the radiological examination that he has aortic  
incompetence

Cases 13, 14, 15, 16, and 17 show that enlargement may  
precede a constant diastolic murmur in cases of aortic  
incompetence It is probable that phonocardiography  
would have helped in earlier diagnosis It is not suggested  
that aortic incompetence should ever be diagnosed in the  
absence of the typical murmur but rather that such appear-  
ances as have been described should lead to repeated careful

auscultation until the diagnosis is certain. These 18 men illustrate difficulties in the assessment and exact diagnosis of doubtful enlargement.

### Discussion

Cardiac hypertrophy of unknown cause has been discussed by Levy and Von Glahn (1937), who give the credit for the first descriptions to Jossier and Gallavardin in 1901. The former authors describe 10 cases in patients aged 29 to 66. Arrhythmias were common. All the electrocardiograms were abnormal. Norris and Pote (1946) discuss four men, aged 21 to 30, who died of unexplained hypertrophy and dilatation of the heart, and all had abnormal electrocardiograms. The clinical features of this condition appear to be rapid progress of symptoms to failure and death, often with embolic phenomena, in a patient with a grossly large heart and an abnormal electrocardiogram. It might be asked whether our first 10 cases should not be included in this idiopathic group, but their symptoms, signs, electrocardiograms, and course would seem to exclude this.

The part played by antecedent hypertension in cases of cardiac enlargement of unknown aetiology has been considered by Kaplan *et al* (1938). Evidence based on microscopical examination is given that previous hypertension played a part in 18 cases out of 45 with such enlargement. They suggest that coronary sclerosis, auricular fibrillation, chronic anaemia, and hyperthyroidism may play a part. Willius (1939) says that it is undesirable to assume the pre-existence of hypertension in any enlarged heart in the absence of collateral physical signs of hypertension. Palmer (1937) showed that coronary sclerosis may cause slight enlargement of the heart. Smith and Bartels (1931) considered coronary thrombosis to be the probable cause of cardiac hypertrophy in two men, aged 35 and 36, seen at necropsy.

### Summary

An account is given of the follow-up examination of 18 men three to six years after they had shown cardiac enlargement without signs of valvular disease or hypertension. The method used was physical examination and radioscopy in the three routine positions.

The causes of cardiac enlargement without signs of valvular disease or hypertension are listed, and the relative value of mensuration and experienced radiological examination in assessing cardiac enlargement is considered.

In 10 cases the enlargement was found to be apparent only in four of these displacement with bradycardia was present, two showed only scoliosis, while in the remaining four the heart was radiologically full sized—two had an aorta more prominent than is usually considered normal in youth, and two had right axis deviation.

In eight cases the enlargement was confirmed—one proved to be a case of familial cardiomegaly which is discussed in detail, one was considered to be probable early mitral stenosis, five (over 25% of the total cases) had developed an aortic diastolic murmur and were confirmed as cases of aortic incompetence in which cardiac enlargement had preceded the diastolic murmur, and one case with similar radiological appearances was thought most probably to have aortic incompetence although no diastolic murmur was heard.

Ultimate diagnosis in the majority of such cases depends on re-examination at a later date.

My thanks are due to Sir John Parkinson for his practical aid and advice in the execution of this follow up.

## CONGENITAL HEART DISEASE SIMULATING FOETAL DISTRESS

### A REPORT OF TWO CASES

BY

A O SANKEY, MRCS, LRCP

Late Senior Obstetric House Officer Hillingdon County  
Hospital Uxbridge Middlesex

Congenital heart disease is comparatively rare according to Price (1937) it is found in about 2% of all patients suffering from organic morbus cordis. Still rarer is it for congenital heart disease to reveal itself *in utero*. The following two cases are of interest in that marked slowness of the foetal heart accompanying congenital heart disease closely simulated foetal distress.

### Case 1

A primigravida at term, aged 21, was seen at a routine visit in the antenatal clinic on July 4, 1947. The fundus uteri was at term, the position right occipito anterior, and the head engaged. The foetal heart could be heard beating quite strongly, but it was markedly slow, the rate varying from 72 to 108, and its rhythm was irregular, the patient did not appear to be in labour. A vaginal examination was made, and the cervix was found to be taken up, but there was no dilatation and no cord was palpable. A diagnosis was made of a probable cord complication—either a loop of cord round the foetal neck or body or a true knot in the cord.

The patient was admitted to hospital from the clinic, and artificial rupture of the membranes with a Drew-Smythe catheter was performed shortly after admission. A 15 minute chart of the foetal heart rate was kept. Labour began at 8 p.m. on July 4, the cervix was fully dilated at 2.30 a.m. on July 5, and a normal delivery of a live female infant, weighing 6 lb 7 oz (2.9 kg) took place at 3.15 a.m. The infant cried well at birth and was a good colour. During labour the foetal heart rate ranged between 60 and 110 but it did not vary with the pains although the rhythm throughout was irregular.

At birth the infant's heart rate was 120 but three hours later it had slowed to 80, on each occasion the rhythm was regular. No meconium was passed during labour and the placenta looked healthy. Cord complications were absent. On examination of the infant shortly after birth there was no cyanosis, the heart rate was 86 and no murmurs were heard.

On July 10 a loud harsh systolic murmur could be heard all over the praecordium, its maximum intensity being beneath the sternum. An electrocardiogram was physiological for an infant of this age and there was no heart block or arrhythmia.

The infant was seen by the paediatrician in the out-patient department one month later. The heart rate was 136 with a regular rhythm. The systolic murmur was still present, there was no change in its quality, intensity or propagation which are characteristic of uncomplicated interventricular septal defect (maladie de Roger). The child appeared healthy and was being breast fed four hourly. She had had no cyanotic attacks.

I saw the child on Sept 2. She was then very well and her weight was 8 lb 5 oz (3.8 kg). She had had no cyanotic attacks.

A skiagram of the chest was taken, and the radiologist reported as follows "The heart shadow is normal for a patient of this age Lung fields clear"

The mother had not had any illnesses during the first three months of her pregnancy

### Case 2

A primigravida at term, aged 38, was seen at a routine visit in the antenatal clinic on Aug 1, 1947. The fundus uteri was at term, the position left occipito-lateral, and the head engaged. The foetal heart could be heard beating strongly at a rate of 44, and it was regular. The maternal pulse rate was 96, and was also regular.

The patient was admitted to hospital, and artificial rupture of the membranes was performed with a Drew-Smythe catheter shortly after admission. Vaginal examination revealed that the cervix was not taken up, the external os was closed, but it was easily stretched to admit one finger, there was no cord palpable.

A 15 minute chart of the foetal heart rate was kept. Labour began at 7 p.m. on Aug 1, and the cervix was fully dilated at 11.45 p.m. A normal delivery of a live female infant, weighing 8 lb 5 oz (3.8 kg), took place at 1 a.m. on the 2nd. The infant was a good colour at birth, and cried lustily after the air passages had been cleared of mucus. The foetal heart rate varied between 44 and 52 during labour, the rhythm was regular throughout both the first and the second stages of labour, and it was unaffected either by the pains or the descent of the foetal head on to the pelvic floor.

At birth the infant's heart rate was 40, and the rhythm was regular, no murmurs were heard. No meconium was passed during labour and the placenta seemed healthy, there was no cord complication. The infant was breast-fed four-hourly, and appeared to be perfectly healthy. On Aug 4 a loud harsh systolic murmur was heard all over the praecordium. The senior physician Dr Barnes examined the child on Aug 7, and reported as follows "Healthy looking infant. No cyanosis. The heart appears enlarged to the left. Apex beat in the fourth left intercostal space in the anterior axillary line. Heart rate slow at 41, but regular. There is a harsh systolic murmur audible all over the praecordium, with its maximum intensity beneath the centre of the sternum."

An electrocardiogram showed complete heart-block, the ventricular rate was 41, and the auricular rate 130, both had regular rhythm. A skiagram of the chest was taken on Aug 13, and the radiologist reported as follows "Heart contours normal in this projection. Lung fields clear."

A diagnosis of interventricular septal defect with congenital complete heart block was made. The infant was seen by the paediatrician in the out-patient department one month later. The heart rate was 42 with regular rhythm, the systolic murmur was still present, there was no change in its quality, intensity, or propagation. The child appeared healthy and was being breast fed four hourly, she had had no cyanotic attacks.

I saw the child on Sept 16. She was being breast-fed three-hourly each feed being complemented with "ostermilk". She had had no cyanotic attacks and her weight was 9 lb 12 oz (4.4 kg). The heart rate was 40 with regular rhythm. A second skiagram of the chest was taken and the radiologist reported as follows "Cardiac outline within normal limits for the age of the child."

The mother's electrocardiogram revealed no abnormality. She had had no illnesses during the first three months of her pregnancy.

### Commentary

In Case 1 the irregularity of the foetal heart together with a rate below 100, strongly suggested foetal distress, and a cord complication was considered the most likely cause. A caesarean section was seriously contemplated as the mode of treatment but, in view of the patient's age and the fact that the duration of the foetal distress was unknown it was decided that an immediate surgical induction should be done and a 15-minute chart of the foetal heart rate was kept. I am quite unable to account for the behaviour of this foetal heart before delivery, for

the presence of an interventricular septal defect without conduction disturbance should not lead to cardiac arrhythmia.

Case 2 is even more instructive, because congenital heart disease was suspected when the foetal bradycardia was discovered in the antenatal clinic (Case 1 having been seen exactly one month previously). In this case the foetal heart was regular and easily audible—quite unlike foetal distress, where irregularity and muffled heart sounds are common characteristics.

Over 100 cases of congenital heart-block have been recorded. The diagnosis, however, is seldom made antenatally, and the case now reported brings the total number of cases diagnosed antenatally to 10. A summary of the main features of these cases, in all of which the diagnosis was confirmed by electrocardiograms, is given in the accompanying table.

Author	Sex	Slowest Foetal Heart Rate	Slowest Rate after Birth	Time of Antenatal Diagnosis	Duration of Life	Remarks
Yater 1929	M	47	47	2 weeks	18 days	Marked cyanosis. Necropsy revealed multiple congenital anomalies.
Witt 1934	M	44	44	2 months	75 days	Infant died in a cyanotic attack. Necropsy revealed coarctation of aorta.
Heubner 1938	No record	80	60	Not given	Alive at 11 months and healthy	Block disappeared at this age.
Ottow 1939	F	32	52	24 hours	Alive at 5 months and healthy	Block still present at 5 months.
Geiger and Hines 1940	F	58	60	17	Alive at 5 months and healthy	Block still present at 5 months.
Thomson 1943	M	60	52	7	1 year	Died of Stokes Adams seizure. Necropsy revealed no interventricular defect.
	F	45	68	4½ weeks	Alive at 4 years and healthy	Block still present at 4 years.
Hammond Stone and Hyams 1944	F	40	40	1 month	Alive at 7 months and healthy	Infant delivered by a lower segment caesarean section shortly after onset of labour because of slow foetal heart.
Plant and Steven 1945	M	50	50	5 weeks	6 days	Died in a cyanotic attack. Necropsy revealed no gross structural defect but histological examination failed to show subendocardial fibres which could be identified as Purkinje fibres.
Saakey 1947	F	44	40	9 hours	Alive at 7 weeks and healthy	Block still present at 7 weeks.

My thanks are due to Dr Barnes and Dr Finlay for their kind help and advice. I am also indebted to Dr Maddocks for the x-ray reports, and to Dr Morgan and the Medical Director, Dr W Arklay Steel, for permission to publish these cases.

*Postscript*—Since writing this article it has come to my knowledge that the infant with congenital complete heart-block suddenly collapsed at home at the age of 4 months and died within 24 hours. The cause of death appeared to be bronchopneumonia, but a post-mortem examination was not allowed.

## SOME ASPECTS OF MORBIDITY SURVEYS

BY

E R BRANSBY, Ph D

*Social Economist Ministry of Health*

Morbidity surveys must be included among newer applications of the social sciences. The contribution made to human welfare by the social sciences is exemplified by such pioneer work as that of Simon and Chadwick on the sanitary conditions of the working classes, of Booth and Bowley on the extent and causes of poverty, and of Cathcart and Orr on the prevalence of undernutrition. Social investigations have had an influential effect on public and official opinion and have been the direct or indirect cause of social planning and legislation over a wide field. The data obtainable from morbidity surveys may well be equally influential in regard to the health services of the nation.

*Health and Sickness*—Before reviewing the various aspects of morbidity surveys it is worth while to consider the definition of sickness or morbidity and its relationship with health, on which opinions differ. Downes and Collins (1940) say, 'Illness as normally understood is an affection or disturbance of health' but Stocks (1947) holds that 'in the definition of sickness the mystical word health, about whose meaning nobody seems to be agreed must be avoided'. But if sickness cannot be defined simply as a departure from health, or an affection or disturbance of health, the implication is that there is some third state, such as being off colour intermediary between health and sickness. It can be argued that sickness should no more be limited to objective physical conditions than undernutrition for example to marked deficiency states. At least for most practical purposes it is sufficient to accept a simple definition like that of Downes and Collins, no matter what may be taken as the definition of health. The important aspect is not the definition but a clear and precise description of the information presented in any survey.

### Types of Morbidity Surveys

The sickness data in morbidity surveys are obtained either from doctors or from lay persons. Some matters affecting clinical and lay diagnosis are considered below.

#### Clinical Diagnosis

Many factors influence the completeness of a clinical diagnosis. Muench (1947) puts the matter succinctly "If we stop to think we must realize that medical diagnosis is definitely stratified into many areas of reliability". Methods of treatment also vary between doctors. Thus in the inquiry into epidemics in schools (Medical Research Council, 1938) ringworm was at first reported only if involving loss of school time, treatment, however, varied so much that eventually cases were reported whether school time was lost or not. Different standards of normality may be adopted—a criticism which has, for instance, been levelled against the clinical assessment of nutrition. All such factors introduce the possibility of non-random bias.

The clinical information on national health insurance certificates has important limitations. It is often vague and indefinite, may relate only to a sign or a symptom the underlying condition being omitted and to an early diagnosis. Bradford Hill (1937) reports 313 cases in which the first diagnoses were gastritis or gastro-enteritis but of which only three quarters would, on the final diagnosis, have remained in the gastric group. Stocks (1947) indeed, emphasizes the advantage of information obtained from lay persons who know the course of the sickness as a whole compared with data based on early diagnoses. Difficulty of classification arises when two or more causes are given for a single condition. In any case, many minor conditions causing only a day or two's absence from work are not certified.

If in a survey it is intended to obtain sickness data clinically diagnosed not only must the possibility of non-random bias

be considered, but also whether diagnoses could satisfactorily be made by an unselected sample of doctors or a group of doctors trained to work to the same standards, or only by one doctor.

#### Information Provided by Lay Persons

In some sickness surveys the sickness data are provided by lay persons, usually housewives in respect of themselves or other members of their family, these data including both diagnoses by doctors and sickness for which no medical opinion has been sought. Such a procedure is beset with difficulties.

*Lack of Knowledge*—(a) In an examination of 1,592 workers all under national health insurance, Morris (1941) found that 112 had major disorders, and of these only 12 were or had been recently under medical care. Of 252 who had varicose veins classified as a minor condition, only 7 had ever consulted their doctor about them. For the most part, the major and minor disorders were neglected or unsuspected. The same sort of thing was found at the Peckham Health Centre. Hence in sickness surveys many real ailments remain unreported. (b) Knowledge of sickness depends on such factors as the extent to which medical advice has been sought and the previous experience of sickness either personally or in others. These depend, for example, on whether the patient has been accustomed to seek medical advice and on the sickness history of the informant's family. (c) Informants in different social groups or different states of health have different standards of normal health, and will report only deviations from these standards.

*Psychological*—(a) Some 'make the most' of sickness, supposed or real, others are proud of their 'good health' and reluctantly report sickness. (b) Some conditions will not be freely reported because of social stigma. (c) The self assessment of health will be influenced by propaganda and the state of morale.

*Effect of Memory*—(a) The longer the previous period about which information is required the less its completeness and accuracy (Sydenstricker, 1926, Downes and Collins, 1940, Stocks, 1947). Stocks suggests that this relates only to minor ailments, but he also suggests that something more than a time factor influences loss of accuracy—for example, the more free reporting during an influenza epidemic and the less free when it is passed. (b) The faculty of recalling events probably depends on the intelligence of the informant, which in turn varies with factors such as social class.

#### Reporting in Respect of Another Person

This assumes unrestricted confidence between the informant and those for whom she is reporting, and that the informant will equally remember their sickness experience. But she may take a special interest in some persons and not in others. Mothers of large families are likely to forget more than mothers of small families.

These factors are very likely to cause bias when associating sickness data with environmental data. Thus a woman of lowly social standing with chronic heart disease may be unaccustomed to consulting a doctor and may be unaware of the nature of her condition, a person in better circumstances may do so and thus be aware of it. A mentally subnormal mother of a large family will forget the ailments of her children, while a mother who voluntarily limits her family will remember the ailments more completely. The mother of a small family or one with adequate domestic help will more readily go to bed if ill than one with a large family, tied to her household duties. This point is well made by Spring Rice (1939), who says "She [the working class wife] firmly believes that her home and family would collapse if her work was interrupted by a sojourn at a hospital or even by the necessity of lying down or resting in bed for a few hours a day, and she therefore refuses to admit that she is ill until these disastrous interruptions to her work can no longer be avoided".

The following two items illustrate how spurious relationships may result by correlating biased data although it is not suggested that the results obtained are entirely due to using such data.

(1) Downes (1947) studied the incidence of chronic sickness among spouses from data collected in a sample survey, only those chronic conditions confirmed by a physician were used in the analysis. The

agnosis of a chronic condition in one spouse will, however, tend towards its easier self diagnosis in the other, thus in turn leading to an examination by the physician

(2) A study of the incidence of sickness of children is reported by the mothers showed that there were "healthy" and "unhealthy" families (Downes, 1945). This would arise simply if some mothers exaggerate and others minimize the sickness experience of their children

#### Detailed Surveys of Selected Population Groups

These surveys have the nature of well controlled investigations. The data collected may relate only to sickness or may include environmental and other aspects. The sickness may be a single condition, a related set, or all conditions. Seldom can all clinical aspects of an inquiry be kept under direct and constant clinical supervision. In surveys among persons living at home, unless there is regular, say daily, home visiting by the doctor, whether or not the doctor is called to the subject depends on a lay estimate of the need, which in turn may vary from person to person. There is undoubtedly great difficulty in getting reliable sickness data for individuals or families living at home. The Ministry of Health, in its nutrition surveys, failed in its efforts to get sufficient of a random sample of housewives to attend a clinic for a limited clinical examination. The difficulties increase if the subjects are expected to attend on several occasions over a period. The scope of investigations involving, say, the family is thus at present very limited.

Groups such as children or work-people who attend a particular place are excellent subjects for study. The kind of data which might be obtained in a study that continues over some length of time would be drawn from three sources: (a) Clinical overhauls, say every six months, these being as comprehensive as possible. (b) Daily clinical examinations to ascertain whether or not a child is sick even though not absent from school. A nurse, in association with the teachers, and with help from a doctor when required, might be able to do this. (c) Clinical assessment of those conditions causing absence from school. Medical certificates, to include the final diagnosis, could be obtained for absence of more than a few days. Uncertified short time sickness could be checked by a school nurse.

#### Surveys Based on Absence from School or Work

In studies of sickness causing absence from school the usual method of inquiry is to track down the causes of absence by means of doctors' certificates, home visits, and notes from parents, enlisting the co-operation of teachers, school nurses, and school inquiry officers. The data collected include medically certified sickness and uncertified sickness based on diagnoses or descriptions of symptoms by the parents which are not considered serious enough to warrant medical consultation. The parents' intimate knowledge and constant appraisal of the child's capabilities and condition are fully utilized, as are the teachers and nurses' knowledge of the various aspects of the child's life. Only sickness causing absence from school is recorded. This is probably fairly complete for certain conditions, such as infectious disease, while for others it may suffice for many purposes. What these conditions are deserves investigation. Absence due to sickness may vary between schools for reasons other than real differences in sickness rates. Thus, the "atmosphere" in one school may encourage children to be absent for minor conditions whereas in others it may do the reverse. A mother may believe that a sick child will be better off going to school than staying in a noisy, restless home while the opposite may be thought by a mother where the home is quiet and restful. School meals may be an inducement for attendance, and so on. The same sort of thing applies in residential schools. Thus even when absence is medically certified differing adjustments may be reached between the teaching and medical staffs on the severity of the conditions that warrant absence and this may vary, for example, owing to school examinations.

The dangers of using absenteeism to measure and compare sickness among work-people have been discussed by Stocks (1944) who speaking of medical certification under the National Health Insurance Act says that the rates are "affected by changing attitudes to the relative importance of keeping at work and of safeguarding the health of the people

affected. These attitudes in turn are affected by economic conditions, amount of unemployment wage rates benefit rates, health propaganda and education." Bishford (1942) shows that such a simple matter as a change in supervision in an office reduced sickness absence by about 50%.

#### Surveys by General Practitioners

The collection of morbidity statistics from general practitioners may well prove a fruitful source of information, limited, of course, to those conditions receiving medical attention. In a recent survey in Canada (Richter, 1948) the demand for health care was compared for two population groups—one representing the panel of several insurance doctors and the other served under the fee-for-service system. Records were supplied by the doctors of all illnesses which received medical attention over a period of twelve months as well as the type of care given.

#### Sample Surveys of Families or Individuals

In sample surveys a random sample of individuals are interviewed in their homes and asked what sickness they or members of their families have experienced over some previous period. The information is usually collected by non-medical investigators, who do not, however, make any "diagnosis of complaints" (Stevenson, 1947) but record what they are told. No definition of sickness is imposed or set up, the informant reporting those conditions of which she is aware and which she "considers to be of sufficient importance to be remembered and designates as such" (Collins 1933). The information coming from lay persons suffers from the drawbacks previously mentioned, and will be subject to many kinds of bias. Moreover as Ryle (1946) points out, "Even though crude assessments may seem justified when the samples are large, the findings cannot then be given a high valuation."

The sickness data are obtained at a single interview relating to the day of the inquiry (Perrott *et al.* 1939) or to a previous period of two or three months (Stocks, 1947), or by a series of visits at intervals of a month or more to collect data over a period of several months (Sydenstricker, 1926, Collins, 1933, Downes and Collins, 1940). The methods of survey are basically the same, although, in some, refinements such as checking the diagnoses by reference to physicians have been introduced. Their accuracy differs according to the effort asked of the memory. The data collected relate (1) to sickness for which medical advice has been sought, representing about 30–50% of the total sickness reported—for most, but not all diseases this is probably reported with sufficient reliability—and (2) to sickness for which medical advice has not been sought, the diagnoses or descriptions of symptoms being based on non-medical opinion. The *Lancet* (1947) suggests "that reliance on the patient's own diagnosis is probably not a source of serious error, for when, in a similar survey in the United States, the diagnoses were referred to the doctor for confirmation, there was agreement [with the patient's diagnosis] in 90% [of cases]". This however, is not so as the 90% relates only to sickness clinically diagnosed and not to the total sickness recorded.

An interesting difference of treatment is accorded to acute and chronic conditions. An acute condition is recorded if it occurs to the knowledge of the informant, but "a chronic impairment of disease generally appears in the illness record only when it causes some distress or is the subject of a medical consultation or examination" (Collins, 1933). A chronic condition even though quiescent, may have greater influence on the way of life than a transient acute condition yet the former is not recorded even though known to the informant, while the latter is.

The question arises as to the relative value of sickness data collected in sample surveys by doctors (Walker, 1947, Sheldon, 1948) and by trained social investigators. The social investigator asks a number of set questions and records the answers without putting her own interpretation to them. Sheldon's (1948) method is as follows: "Apart from what was actually visible the only information available was the account by the individual of his symptoms. Once the interview was well under way most subjects were willing to describe their complaints (if any) and answer questions in such a way that an intelligent guess of the underlying diagnosis could usually be

made. The doctor can thus use his medical knowledge to develop the interview in the most profitable directions. Further, in spite of the obvious limitations of a survey by interview only, the results merit description since they illustrate the extent to which various types of complaints restrict the activities of old people. This raises the interesting point, To what extent could the symptoms be satisfactorily recorded by lay persons? Sheldon states that he found considerable discrepancies in the sickness data recorded by himself and by lay investigators, but gives no details. His own inquiry was limited to conditions confirmation of which did not depend on clinical examination, but he suggests that an expert examination including a physical examination of a random sample might be possible for certain conditions. Is it possible that lay persons can satisfactorily obtain information on certain conditions, the symptoms of which are readily recognized and assume importance only when the patient is aware of their presence? It is to be noted that in the investigations on the common cold (Andrewes, 1948) the lay subjects record their symptoms, and the doctor then decides whether or not they had a cold.

### Formulation of the Problem

The planning and execution of a morbidity survey require that the purpose and objectives of the survey be defined with clarity and precision, that the scope and limitations of the method of survey be recognized, and that the survey as planned will in fact give the information which it is intended to obtain. What is eventually included will be a compromise between what the investigator would like to conclude whether the criteria can in fact be assessed or measured, and whether the facilities are available for doing so. This process can be illustrated by a proposed inquiry into the loss of working capacity due to chronic sickness. To be decided are the definition of chronic sickness and the criteria for loss of working capacity. There is no hard and fast definition of chronic sickness, and it is feasible that the meaning adopted will depend on the objects of the inquiry. In some employments the loss of working capacity may be directly measurable by loss of output, but in others it may be possible to measure only loss of working time—that is absenteeism—and it may or may not be possible to assess how much of this is due to chronic sickness. Even then what causes incapacity in some employments may not do so in others. The final form of the inquiry may thus be greatly restricted and the results open to many reservations.

### Discussion

The purpose of morbidity surveys is to provide data on the incidence, social pattern, and method of spread of sickness, and thus produce a basis for the planning of the health services. This falls into two parts, the action required to prevent disease and the services necessary for treatment, or as Ryle (1946) puts it, "social planning and political action." The various kinds of surveys are not alternatives but provide information of different kinds, each contributing to the picture as a whole, but only to the extent that the information presented is reliable. Small detailed surveys, especially if the results are tested by repeated inquiry, are obviously of special importance.

There is an urgent need for research into all aspects of morbidity surveys, not only in regard to methods of field inquiry but also in regard to related matters such as the criteria for various environmental factors and the statistical treatment of data. The recent difference of opinion between Woolf and Waterhouse and Buckatzsch (Buckatzsch, 1947) on the method of estimating the effect of inter-correlated social data on infant mortality illustrates the need for statistical research, the application of which to social inquiries has been neglected. The dearth of essential "tools" is due in part to the urgency of the tasks which have faced social scientists, which has led them to "get on with the job" instead of devoting their energies to developing and assessing methods. The future of social surveys, including morbidity surveys, depends on the developing and testing of techniques. The aim in social

inquiries should be to impose the same standards of controlled experiment and investigation as are applied in the natural sciences.

## EPILEPSY AND TETANY

BY

J. E. G. PEARSON, D.M., MRCP  
 Late Wing Commander R.A.F.V.R.

The following case report shows that the true significance of an attack of "symptomatic" epilepsy may long remain latent.

### Case Report

A flight lieutenant in the R.A.F. aged 24 was admitted to an R.A.F. hospital on July 11 1947 with a story from his medical officer that a batwoman who had gone to remove his supper tray had found him in bed in a semiconscious state, and when she approached him he made as though to strangle her, for this reason he was put in charge of the neuropsychiatrist.

On questioning he denied any memory of this attack, after which he felt weak but not confused nor did he complain of headache. For three days previously he had complained of some malaise, nausea, anorexia, and later vomiting, followed by the most striking symptom at this stage—hiccups. He had not bitten his tongue or been incontinent in this attack, but he gave a history of a similar chain of events two years previously while overseas ending in an attack in which he bit his tongue. On account of that epileptiform event he had been invalided home. During the intervening period he claimed to have had perfectly normal health and had taken no medicine or tablets.

His past history showed nothing to suggest petit mal, and he had not suffered from fainting attacks or headaches. He had never sustained a head injury. He had had diphtheria and pneumonia as an infant and his appendix had been removed for an acute attack without complications three months before admission.

Examination showed a well built man with no evidence of loss of weight. There was some dryness of the mouth (to which he attributed his slight dysarthria) with a healed scar on his tongue. Mentally he seemed rather apathetic and slightly drowsy, and was hiccupping 20 to 30 times a minute. Blood pressure was 120/80. No other abnormal physical signs were found in any system on clinical examination.

During his first three days in hospital numerous measures were tried to control his hiccup which persisted even during sleep, but no treatment had any prolonged effect. He was encouraged to eat what he could manage of light diet and to take plenty of fluids as the vomiting had ceased since admission.

On July 14 he was still a little drowsy and dry in the mouth. His blood urea was 85 mg. per 100 ml. blood sugar 130 mg. per 100 ml. and his urine contained a cloud of albumin. A general

medical opinion was here sought, it was considered that these findings, together with his clinical state at the time were accounted for by the degree of dehydration present, and although his hiccup had become much less frequent (possibly owing to thiopentone and cyclopropane anaesthesia), 2 pints (1.14 litres) of normal saline solution were given intravenously on July 16. Soon after this his clinical state returned to apparent normality and he felt fit. Four days later his blood urea was 20 mg per 100 ml and his albuminuria had disappeared. During this period examination of cerebrospinal fluid, blood WR, and intravenous pyelogram were all negative.

As he felt so fit and had a long-standing arrangement to start a 10-day holiday on July 31, he was allowed to leave the hospital with the idea of readmitting him afterwards for further investigations. While at home on the very night of his discharge he again developed nausea and hiccup and vomited about 15 times during the subsequent 36 hours before being readmitted.

The striking feature now was the presence of marked tetany, attacks of which he had been having for about 12 hours previously. The condition was symptomatically relieved by the intravenous injection of 10 ml of 10% calcium gluconate but three further attacks were witnessed within the next 24 hours evidently initiated by the effort of vomiting. The extremities assumed the typical posture, the breathing became laboured, cyanosis was marked, and consciousness was lost within a minute. The pulse was 54, with some premature systoles its volume remaining good. After about three minutes gradual relaxation occurred, his colour improved, and his jaw, clenched at first, started a regular munching movement but there were no true clonic movements of this organ or of his limbs. Unconsciousness remained for about 15 minutes, with eyes rolling and squinting but with normal-sized equal pupils. There was no laryngeal stridor. His blood pressure during the recovery phase was 120/80.

The clinical diagnosis of tetany from alkalosis with hypochloraemia, was confirmed by the biochemical investigations.

Only one attack occurred after the start of intravenous drip saline with 10 ml of 10% calcium gluconate per pint (568 ml), and within two weeks his blood chemistry had returned almost to normal all symptoms having subsided.

During this exacerbation of symptoms the time had naturally come to review the nature of his attack in Egypt two years previously and any other relevant past history. He was himself quite definite that the prodromal events leading up to all his attacks had been very similar, and on direct questioning he remembered having had tinglings in his hands feet and lips before his original attack, though never any cramp. The description by the sister who witnessed the end of the attack had been recorded as a "convulsion, during which he was unconscious with eyes open and face twitching for one minute, followed by a period of confusion in which he answered only 'Yes' or 'No'". The tongue had been bitten, but there had been no incontinence.

No abnormality had been found on examination of the central nervous system and there was no pyrexia. A blood smear had been negative for malaria parasites, and examination of the CSF had shown normal pressure, cell count, protein and chlorides. He had been invalided home on account of this epileptiform attack and made permanently unfit for flying duties. On return to this country radiographs of the skull and an electro-encephalogram had proved negative as also had clinical examination by the consultant in neurology.

The cause of his attacks of vomiting remained the final matter for elucidation, he was most definite that he had had no vomiting whatsoever in the intervening two years and had never suffered from diarrhoea, indigestion, or any abdominal pain. In spite of this the solution was apparently found in a barium meal which showed a small prepyloric ulcer, with a large atonic stomach, a great quantity of resting juice and a considerable barium residue in the stomach at eight hours and some at 24 hours even after a course of routine medical peptic-ulcer treatment for three weeks with full doses of belladonna.

On Oct 7 the abdomen was opened through a transverse incision and a partial gastrectomy was performed. A prepyloric ulcer was demonstrated in the prepyloric region anteriorly, a well-developed cholecysto-duodenocolic membrane was found binding down the first part of the duodenum.

At this point the duodenum was constricted and partially obstructed owing to thickening and fibrosis in its wall for about 4 cm, the parts distal to this being of normal calibre and consistency.

The findings were confirmed by examination of the excised specimen, the healed gastric ulcer did not appear to be producing pyloric stenosis, and it was presumed that the obstruction was caused by the organic changes in the duodenum secondary to the membrane as described.

### Comment

This case shows two main points of interest. First, the fact that his original attack was of an epileptiform nature, which in the light of after events could confidently be assumed to have been of tetanic origin. While true convulsions are so well known in children as part of a tetanic state, it is undoubtedly easy to overlook this possible cause for them in adults, although briefly mentioned in some textbooks. Support is also lent to the opinion that it is unwise to stamp as an "epileptic" a patient who has an isolated convulsion—a point emphasized by Rook (1947).

Secondly, it was natural to presume from the x-ray appearance that pyloric stenosis secondary to a prepyloric ulcer was basically the cause of all his troubles, it was considered at operation, however, that this was not the true explanation but that his obstructive symptoms were due to a duodenal stenosis, secondary to a large persistent cholecysto-duodenocolic membrane. In either case the marked lack of abdominal symptoms apart from his attacks was difficult to explain. The subject is fully reviewed by Mahoney (1946), who considers that this membranous fold occurs in at least 18% of people, but only occasionally gives rise to symptoms. Of the 18 cases which he reports as pathological, the symptoms in the great majority simulated either chronic cholecystitis or duodenal ulcer.

I wish to thank Group Captain F W P Dixon for the surgical notes on this case, and Squadron Leader T S L Beswick for the pathological investigations.

## Medical Memoranda

### Liver Abscess Sporadic Amoebiasis

From time to time sporadic cases of amoebiasis have been recorded in the British Isles. It seems likely that with the return of troops from tropical service in the post-war years the incidence will increase. The following case is of interest in that no tropical connexion or association could be discovered.

### CASE REPORT

A man aged 34 was admitted to hospital with a history of sudden onset of epigastric pain five days previously. His pain was associated with vomiting and was worse on deep inspiration. Up to the onset of the pain he had been in good health and had noticed no alimentary upset of any description.

On examination he was seen to be well nourished though sparsely built, and his complexion was pale. The tongue was coated and dry. The abdomen moved well but there was muscle-guarding and resistance over the right hypochondrium. No mass was felt and the liver was not palpable. The remainder of the abdomen was soft and not tender. White blood cells numbered 27,000 (81% polymorphs). X-ray examination showed no gas under the diaphragm, although the diaphragm was raised about 1 in (2.5 cm). Temperature was 100° F (37.8° C), pulse 100. A diagnosis of probable leaking duodenal ulcer was made, and expectant treatment adopted. His general condition, however, did not improve, and five days later the abdomen was opened.

**Operation.**—The abdomen was explored through a paramedian incision. A large soft liver was found to reach to the right iliac fossa. It was so soft as to be impalpable even under anaesthesia. The peritoneal cavity and abdominal viscera were otherwise normal. The right lobe of the liver was then explored with a wide-bore needle and 5 pints (2.84 litres) of anchovy sauce pus were aspirated. On probing with the finger a further loculus was entered.

which yielded another pint (570 ml) of yellow pus. On this latter finding the cavity was drained after the instillation of 100,000 units of penicillin.

Convalescence following operation was uneventful. The pus from the abscess was sterile and yielded no amoebae. Repeated examinations of the stools failed to demonstrate the entamoeba, either in the cyst or vegetative form. A-ray examination of the bowel showed no pathological change. Sigmoidoscopy at this stage revealed the smooth pale, glassy and rather rigid mucous membrane associated with chronic amoebiasis. A full anti amoebic course was therefore given, the response being immediate and dramatic.

This patient was carefully questioned in order to elicit a possible source of infection. He lives in a Surrey suburb. Neither he nor any of his family has ever been out of the country nor have any of his friends or business associates. He had no illnesses or symptoms until the day of admission to hospital.

C F CRITCHLEY M.S., F.R.C.S.  
Honorary Surgeon  
Sutton and Cheam General Hospital

### Cure of Exomphalos in a 2-hours-old Infant

The following case is worth recording, as the patient, so far as we know, was the youngest to be anaesthetized successfully with cyclopropane. It also shows that children do stand a fair amount of handling of the viscera.

#### CASE REPORT

A full term female infant was admitted to Dulwich Hospital on Dec 7 1947, with an exomphalos. On examination the abdominal

FIG 1—Showing the exomphalos before operation

viscera were lying on the abdominal wall covered by transparent membrane (Fig 1). The striking feature was that the major part of the liver was lying outside the abdomen.

**Operation**—The child was operated on two hours after birth under cyclopropane and oxygen anaesthesia administered by Dr J Pinev. An incision was made along the edge of the exomphalos and the membrane excised. The liver and then the intestines were returned to the abdominal cavity with some difficulty and the wound was closed with through and through silk worm gut sutures. In

FIG 2—Showing the condition three weeks after operation

spite of the considerable handling of the viscera the child made an uneventful recovery. Fig 2 shows the condition three weeks later. At the time of writing the child is 6 weeks old and is progressing satisfactorily.

We wish to thank Dr J Pinev for his excellent anaesthetic. Dr O W Roberts for permission to publish this case and the nursing staff for their post-operative care.

### A Case of Rupture of Muscles of the Forearm

Rupture of muscles and tendons without breaking the skin is not uncommon. In the case of the long head of the biceps brachii, the plantaris, and the rectus femoris it presents well recognized clinical features. I had not previously seen a case of rupture of muscles of the forearm, nor have I found it described in a somewhat limited search of the literature. Mercer (1943) does not mention any of the forearm muscles in a list of "those most frequently affected." The following case is reported because of its rarity, the clinical features seen, and the satisfactory result after a severe injury.

#### CASE HISTORY

A private soldier aged 21 was driving a 15 cwt truck when it went over a milestone and overturned, late on the night of June 19 1947. He is unable to tell how his arm was injured because "every thing happened so quickly," but as the milestone was less than 1 ft (30 cm) high it is likely that the wheel was very powerfully jerked in his hand. When seen in hospital about 14 hours after the injury, he complained of 'pins and needles' in the fingers of his left hand.

His general condition was good. The left arm was very swollen from a few inches above the elbow to the finger tips. The skin was pink and flushed. There was only a flicker of movement in the fingers and thumb. The radial pulse was present at the wrist. Radiographs showed no bony injury. A provisional diagnosis of subfascial haematoma was made. The limb was elevated on pillows and efforts were made to do finger movements. Next day (June 21) the limb was rather more swollen, the paraesthesia was unaltered. The radial pulse was still easily felt. Exploration was considered advisable.

**Operation**—At noon on June 21—i.e., about 36 hours after the injury—a longitudinal incision was made over the maximum swelling on the antero-medial aspect of the forearm, from about 1½ in (3.75 cm) above the elbow to 4 in (10 cm) below it. The skin gaped immediately, revealing rather congested superficial veins and deep fascia which was tense over a haematoma. The fascia was incised in the same line, and it was then seen that the large blood clot lay among ruptured pieces of muscles. The clots were removed and it was found that the palmaris longus lay intact over the tattered and separated ends of the flexor digitorum sublimis and the flexor carpi radialis. The rupture appeared to have occurred a little above the middle of the forearm. It was clearly impossible to make a good repair of the injured muscles, and in any case it seemed inadvisable to risk any avoidable post-operative swelling. Haemostasis was secured and the skin sutured, there was a little tension in places.

The limb was placed on pillows and active finger exercises were encouraged. Within a day the paraesthesiae had gone. In about four days the swelling of the hand had subsided. On the ninth day a plaster cast was applied to prevent flexion deformity at the wrist. Finger movements were improving but weak. After 24 days there were two hard masses of fibrous tissue in the forearm, and the fingers were showing a flexion deformity unless the wrist was palmar flexed. Frequent stretchings were done by the patient and the physiotherapy staff. Splintage was at this time avoided as it was considered advisable to encourage finger movements continually. After seven weeks a night splint was used to keep the fingers straight with the wrist straight. After nine weeks the grip was 50 to 60% of normal. The index finger was flexed 30 degrees at each interphalangeal joint when the wrist was straight—the other fingers were straight. Ionization with potassium iodide was tried in the hope of reducing the scar tissue a little.

When seen three weeks later (Sept 19)—i.e., three months after the injury—the index finger was straight when the wrist was straight but only in the mornings after a night on a splint. After use it became flexed. With the wrist dorsiflexed all the fingers became slightly flexed. There was no palpable activity in the flexor carpi radialis. The patient was able to use the fingers well both individually and together. He had an excellent grip about 80% normal (he is right handed). He was practising finer finger movements on a typewriter and was making rugs.

Improvement was still taking place when he was last seen. While a degree of limitation of extension of the fingers and wrist seems inevitable, it is likely that he will have a very strong and useful hand with little disability after a period of two to three months.

This case is published by permission of DMS, BAOR, and C/O C 25 (Munster) Military Hospital.

## Reviews

### SURGERY OF THE ABDOMEN

*Surgical Treatment of the Abdomen* Supervising Editor, Frederic W Bancroft, A B, M D, F A C S Associate Editor, Preston A Wade, A B, M D, F A C S (Pp 1026, 457 illustrations and 3 colour plates £5 10s) Philadelphia and London J B Lippincott Company 1948

There are not many absolutely up-to-date textbooks to which a practising surgeon can turn for detailed information on operative procedure, but this is one—a very comprehensive and helpful one. It is written by a number of authors, each an authority and known to all readers of American surgical literature. The editing has been very well done, for the unevenness of presentation expected in a book by several authors is noticeably absent. All the procedures described are sound and well established, there is no place for freak operations.

The editor, introducing the account of porto-caval anastomosis, gives a warning that outstanding skill and craftsmanship are needed but says the operation is described because it is past the experimental stage. It is difficult to think of any abdominal operation not discussed, but there is no account of abdominal lumbar sympathectomy, nor of ligation of the vena cava nor of the attack on a prolapsed intervertebral disk from the front. However, it may well be that the two latter operations will never be established as routine measures. The usefulness of the book is greatly enhanced by discussion of the surgery of the oesophagus and mouth. These sections of the book reach the same high standard. There are also excellent accounts of pre- and post-operative treatment and best of all, a chapter called the "Fundamental Principles of Surgical Technique". It is curious to read in a book coming from the country where John B Murphy practised that proctoclysis is ineffectual and not in use now. We can conclude only that modern surgeons have had no experience of this valuable method. It would be a cautious critic who could find anything for serious adverse comment in this outstanding production.

### NUTRITIONAL DEFICIENCY

*The Pathology of Nutritional Disease* By Richard H Folliott Jr M D (Pp 291 illustrated 35s) Oxford Blackwell Scientific Publications

The author of this book discusses the chemical and anatomical changes caused by deficiencies in the food. The deficiencies considered include the elements (both those that make up the bulk of the mineral matter of the body and the trace elements), amino acids and vitamins. He discusses the functions of these factors and describes the disturbances of metabolism and macroscopic and microscopical abnormalities found in experimental deficiencies. He considers only the mammalia except that he refers to birds when necessary for the sake of completeness as in the case of vitamin B<sub>1</sub>. He treats thoroughly of the changes found in mammalia other than man but in general he considers only those changes in man that can be ascribed with some certainty to deficiency of the factor under discussion and has tried to steer clear of controversial points so far as possible. However he discusses fairly fully the relation of changes in the nervous system to deficiency of vitamin B<sub>1</sub>. He questions whether Wernicke's syndrome is the result of this deficiency and is sceptical about the prevalence of cardiac manifestations of vitamin B<sub>1</sub> deficiency in the U.S.A.

Professor Folliott can justly write at the end of many sections words to the effect that it is improbable that deficiency of a particular factor occurs in man. He might therefore have found more space to discuss those changes in man which he considers to be due to a single factor. Two short paragraphs only are given to an account of sodium deficiency which is of practical importance and has been studied thoroughly. He considers keratinizing metaplasia in man very briefly. This matter is particularly interesting since many morbid anatomists regard it as the result of inflammation or irritation whereas students of pathology maintain that it is produced by deficiency of vitamin A. The occurrence of follicular keratosis in experimental deficiency of ascorbic acid might be mentioned. Swelling and bleeding of the gums have been features of human scurvy since

the days of the crusades, they are promptly cured by ascorbic acid. The account of the relation of gingivitis to ascorbic acid might have been allowed more than one sentence.

The book is well illustrated. Photomicrographs of sections of the costo-chondral junction, which are considered to show changes due to minor rickets, are particularly interesting for it is improbable that such changes could be detected by x-ray examination. It is on the basis of such changes that rickets was diagnosed in over 40% of children dying in Johns Hopkins Hospital during 1923-42. There are minor faults which might be corrected in later editions. Whatever Fuson and Christ synthesized (p 91) in 1936 it was not vitamin A. The author of the paper referred to on p 94 (Ref 551) does not discuss the corneal changes due to deficiency of vitamin A.

J R MARRACK

### ION TRANSFER

*Treatment by Ion Transfer (Iontophoresis)* By D Abramowitz M D, and B Neoussikinc, M D (Pp 186 £1 10s) New York and London Staples Press 1947

In this book the authors give a very full and detailed account of treatment by means of ion transfer (or ionization as it is commonly called in England). In Part I they describe the history of its development and discuss the physical aspects of the subject. In this part of the book the authors seem to be thoroughly at home with their subject and their descriptions of the biophysics of the behaviour of the electrical current in human tissues are authoritative, and they also describe well the action of various ions used in treatment.

In Part II the authors describe clinical applications of their techniques. This part of the book is not so useful as the first. Too many conditions are said to respond favourably to ion transfer, and critical appraisal of results is lacking. Pathological terms are too vague and claims apt to be sweeping. Thus we are told that 'electrolytic penetration of calcium is applicable in neuralgia, delayed knitting of bone fractures, arthritis, and brain disorders (hemiplegia, epilepsy, etc.)'. Similarly we read of the treatment of arthritis resulting from rheumatism and gout. The text is clear and the bibliography and index are full.

W TEGNER

### HORMONES AND NEOPLASMS

*Endocrinology of Neoplastic Diseases* A symposium by Eighteen Authors Edited by G H Twombly, M D, and G T Pack, M D Oxford Medical Publications (Pp 392 illustrated £3) New York Oxford University Press London Geoffrey Cumberlege

The possible endocrine background of malignant disease has come more and more to the fore in recent years, and this branch of study has been encouraged by the discovery of the dramatic effects produced by oestrogens in cases of carcinoma of the prostate. The literature on the subject is wide and scattered and presents great difficulties to anyone other than an expert. As with most new subjects the quality of the literature on endocrinology varies widely and it is necessary to know the standing of the author of a paper before one can take the results seriously.

The present volume is a welcome addition to the literature, since it provides this authoritative guidance and presents the general reader and the expert with an up-to-date account of the subject. The literature reviewed has been extended from the original series of monographs first published in *Surgery* in 1944, and includes that appearing up to 1946. The articles are models of their particular type and the lists of references are in practically every instance encyclopaedic. Most of the individual articles have over 100 references each and the authors have in all cases given an excellent historical summary, almost invariably giving references to the original papers where the disease was first described. For example in the chapter on parathyroid enlargement, by Oliver Cope, the references start with one to Sandstrom's work, and one can find references also to Von Recklinghausen's original paper and that of Mandl. Starting from these, one has all the papers of greatest importance up to the present time. It is very interesting indeed for general readers to be able to find the original papers of say, Addison, Gull and other pioneers.

The first short introductory chapter is followed by one on tumours in experimental animals receiving steroid hormones, and then one on the investigations into the role of the pituitary

in tumorigenesis. After this follow special chapters on the various types of tumours—namely, pituitary, ovarian, uterine, breast, prostatic, testicular, adrenal, thyroid, parathyroid, pancreatic and pineal. All the articles are without exception first class and it would be invidious to pick out any one for special mention.

E C DODDS

### DUNDEE ROYAL INFIRMARY

*Dundee Royal Infirmary 1798 to 1948. The Story of the Old Infirmary with a short Account of More Recent Years.* By Henry J C Gibson (Pp 71, illustrated.) A certain number of copies are available without charge on application to Dr H J C Gibson at the Royal Infirmary Dundee.

By an interesting chance the handing over to the State of the Dundee Royal Infirmary coincides almost exactly with its hundred and fiftieth anniversary. Inspired by this double event the medical superintendent of the hospital, Dr Henry J C Gibson, has published in an attractive little book the story of the hospital—a story that might well pass for a synopsis of hospital development in this country during these hundred and fifty years. *Mutatis mutandis* it could be told of a hundred others of our large hospitals. There is for example the modest origin in this case a development from an earlier dispensary for the sick poor started in 1735, the remarkable growth and expansion from a small two story house catering in two small wards for 20 in patients to a large, handsome edifice built between 1852 and 1855 to accommodate 280 patients and expanded and developed since then so that the hospital now handed over provides well over 500 beds, and the story of the steady growth of specialism and the special departments. These changes are illustrated by interesting charts and tables, and a number of portraits and photographs add to the value of the book as a record.

One is reminded of the close and friendly association with their Dundee colleagues of two famous Edinburgh professors, Christison and Syme. Both were consulted on a number of problems, and together they advised on the plans of the 'new' Infirmary. Consultation, however, was not confined to Edinburgh. Advice was also sought of Glasgow in the person of Sir William Gairdner, and the task of building the present Infirmary was entrusted to a London firm of architects. The author refers to some of the more colourful early members of the staff among them John Crichton. A skilled lithotomist, Crichton combated the excessively cautious teaching of Astley Cooper and claimed to have 'experienced the satisfaction of seeing affections which were considered insuperable objections to an operation gradually give way after the pain and irritation, occasioned by the original disease have been removed'. Here surely is prescience of the therapeutic triumphs of surgery that were to come.

Yet into the reader's mind, as the tale of progress and development unfolds, there steals the whisper "plus ça change, plus c'est la même chose". Consider this, written in 1797 by a benefactor in Bombay, 'You have judged very rightly in electing for short periods the different officers of your hospital for I have observed where allowed to continue for life or for a long time that the business falls at last under the direction of some individual who generally manages it ill. Have we solved the problems of administration? Is the urge to more and more specialization in the best interests of medicine? Do we still need two kinds of nurse, as they did in 1798? At any rate we may hope with Dr Gibson that the spirit of the hospital has not changed and will not change, and that 'the relief of suffering will continue the paramount concern of all who serve this house'.

E R C WALKER

When it was first published during the war there may have been a use for *Standard Radiographic Positions* by Nancy Davies, MSc, C.T. and Ursel Isenburg, MSc (second edition, 21s, Baillière, Tindall and Cox) among Service personnel who were unable to take the normal two year course in radiography, but it is difficult to recommend it now to radiography students. It is too elementary and has not been brought up to date in this second edition. The authors do not mention phenol, nor do they describe tomography. The exposure chart given at the end of the book suggests a lamentable lack of knowledge of modern technique—witness that recommended for chest and barium meal examinations. The modern student will want something more than this if she is to defeat the examiners for the MSc.

### BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Modern Clinical Psychiatry* By A P Noves M.D. 3rd ed (Pp 525 30s) London W B Saunders 1948  
Based on lectures in psychiatry delivered to medical students

*Science News* Edited by J L Crammer (Pp 158 1s 6d) London Penguin Books 1948

Articles for the layman on a variety of topics including demography, viscosity, and group psychotherapy.

*Legislación sobre Seguridad e Higiene del Trabajo* By Ministerio de Trabajo (Pp 202 No price) Madrid S.cción de Prevención de Accidentes e Higiene del Trabajo 1948

The regulations governing industrial health and hygiene in Spain

*Living Anatomy* By R D Lockhart M.D., Ch.M. (Pp 71 12s 6d) London Faber and Faber 1948

Labelled photographs of the nude body illustrating surface contours and muscular action

*Die Primäre Tuberkulose bei Erwachsenen und Kindern und ihre Entwicklung* By St J Leitner (Pp 157 15 Swiss francs) Berne Hans Huber 1948

Report of an investigation into primary tuberculosis in 160 adults and adolescents and 106 children

*Malignant Disease and its Treatment by Radium* By Sir Stanford Cade, KBE, CB, FRCS MRCP Vol 1 2nd ed (Pp 383 52s 6d) London Simpkin Marshall 1948

The first of four volumes, contains Part I, on the radioactivity of radium, and Part II, on the biological effects of radiation

*The Medical Clinics of North America* Mayo Clinic Number By various authors (Pp 305 No price) London W B Saunders 1948

Includes a symposium on anomalies of the heart

*Textbook of Pharmacology and Therapeutics* By H N Wright MSc, PhD, and M Montag RN MA 4th ed (Pp 720 20s) London W B Saunders 1948

This edition contains much new material on drugs introduced into therapeutics in the last few years

*Nursing of Children* By G Sellw BS, RN PhD, et al 6th ed (Pp 486 20s) London W B Saunders 1948

A textbook for nurses

*Nursing History* By M Goodnow, RN 8th ed (Pp 404 17s 6d) London W B Saunders 1948

A short history of nursing throughout the world

*Hygiene and Health Education for Training Colleges* By M B Davies, BSc 4th ed (Pp 438 9s 6d) London Longmans, Green 1948

An outline of health education intended particularly for teachers in training

*Childhood and After* By S Isaacs, CBE MA DSc, Hon DSc (Pp 245 15s) London Routledge and Kegan Paul 1948

Studies on the psychology of young children

*An Apple A Day* By P Gosse (Pp 195 10s 6d) London Cassell 1948

Stories and reminiscences from the author's varied life

*Correlative Neuroanatomy* By J J McDonald, MSc M.D. et al 4th ed (Pp 156 53 00) California Univ. Medical Publishers 1948

A students' manual relating the physiology and anatomy of the nervous system to clinical signs and symptoms

*Medicine and Science in Postage Stamps* By W J Bishop, F.L.A., and N M Matheson, FRCS (Pp 82 7s 6d) London H K Lewis 1948

Includes many illustrations of stamps of medical interest

## BRITISH MEDICAL JOURNAL

LONDON

SATURDAY OCTOBER 9 1948

## HABITABILITY OF SHIPS

Macdonald Critchley<sup>1</sup> in his Croonian Lectures described the hardships due to extremes of climate which the seamen serving in the ships of the Arctic convoys and in the Indian and South-West Pacific Oceans had to endure. The reports from the Tropics in some respects disclosed a new experience, because before the second world war no sea battles had been fought in modern steel steamships in tropical waters. In the 1914-18 war action stations in the temperate climates of the North and Mediterranean Seas had not been in any way intolerable. However, the possible effects of hot climates combined with the "wild heat" which escapes from the machinery of the ship herself and accumulates between decks had been carefully examined in peacetime, and the means of maintaining a satisfactory atmospheric environment in the key positions of the ship during action had been fully investigated.

The conclusions reached in peacetime were that the conditions, if uncomfortable, were not intolerable, and that they did not entail a degree of hardship which the traditional tough and climate-conditioned British seaman of high morale would not be prepared to accept willingly in the day of real battle. When, therefore, in the 1939-45 war lurid stories and bitter complaints of the conditions between decks arrived from ships serving in the Tropics, old and experienced sailors at Admiralty headquarters were at first doubtful about how far these reports should be accepted as factual or as the time-honoured "grouses" which were the recognized safety-valves of all men on active service abroad. However, the Royal Naval Personnel Research Committee of the Medical Research Council was asked to investigate the climatic conditions in warships in the Tropics. Some of the valuable scientific work carried out has been described recently in this *Journal* by Surgeon Commander F. P. Ellis,<sup>2</sup> naval secretary to the R.N.P.R.C. and the naval medical officer in the team of naval and civilian expert observers responsible for the field work. This team confirmed that the complaints and anecdotal evidence were not overstatements. Indeed, scientific tests showed that the heat and atmospheric conditions between decks had more serious physical and psychological effects on fighting efficiency and health than had been indicated by the subjective feelings of the ship's company themselves. There had been failure at the Admiralty for many days to envisage the difference in the atmospheric environment during peacetime manœuvres and action in tropical seas. The exercise of action stations in peacetime was for an hour or two once a week. In war, action stations were of daily occurrence and lasted for

hours at a time. Blackout and "war damage precautions" interfered continuously with proper ventilation. There was no let-up from these austere living conditions in war such as occurred during the pleasant health cruises to cooler parts of the station, with plenty of leave, healthy recreation, and jaunts ashore, which were part of the peacetime routine on hot stations. Again, with ship's companies made up of 85% unseasoned conscripts, the crews were themselves of very different composition in peace and war.

The results of the investigations of the R.N.P.R.C. team of observers combined with the evidence of experienced sea captains on naval operations in tropical waters proved that extensive air-conditioning was the only way of maintaining the minimum effective temperature compatible with the maximum efficiency of a warship on active service in the Tropics. In order to compare the conditions in different types of ships serving in the same or different climates some simple objective index entirely dependent on the human element was found to be necessary in addition to the physical and mechanical measurements of habitability such as effective temperature.<sup>3</sup> For psychological reasons no reliance whatever can be placed on the subjective sensations of any single individual, whoever he may be. An admiral or a stoker may equally be a robust insensitive optimist or a weary nervous pessimist, with corresponding feelings and opinions concerning the same physical environment. The present problem of the effect of powerful heat-producing engines on the health of the ship's company attracted attention from the first introduction of steam into the Royal Navy. Admiral J. B. Sullivan, in 1854, reported to the Admiralty that "it is the large screwships which have been unhealthy. It is the heat of the engines confined under the deck which seems to cause it." This observation can never be repeated, because only during the actual switch-over from sail to steam could the ill effect of "wild heat" on the health of seamen be properly controlled by the presence in the same squadron of the old sailing ships in which no "wild heat" could accumulate.

The sick returns have for long been used as an unbiased gauge of the healthiness of different types of ship, but in some ways the ordinary sick lists are unsatisfactory measures of habitability. The naval medical administration therefore decided, largely on the results of the data collected by the R.N.P.R.C. observers, that the "attending list" might be a more convenient or sensitive index of healthiness or habitability than the sick list. The attending list in naval parlance refers to men with minor ailments or injuries who are not ill enough to be retained in the ship's sick bay or sent to hospital. The attending lists, not being considered important, were usually kept in an irregular and haphazard way, and before they could be used as a comparative index of habitability a simple standard method of recording had to be devised and instructions issued to the medical officers of all ships regarding the way they were to keep the lists and make returns to the medical department of the Admiralty.

The full details of this new statistical return and the conclusions reached after it had been given a trial are embodied in a report prepared by Dr J. A. Fraser Roberts for the R.N.P.R.C. and published recently in the *British*

<sup>1</sup> *Journal*, 1948, 2, 145-152.

<sup>2</sup> *Journal*, 1948, 2, 153-159.

<sup>3</sup> *Journal*, 1948, 2, 159-160.

*Journal of Social Medicine* <sup>4</sup> First, this new index of social health was found to give practical information about ship habitability, and in spite of the short time it was in use clearly showed that the attending list doubled in size in the passage from temperate to tropical waters within a week or two. Skin diseases, always a bugbear in the Tropics, showed a triple increase. As Fraser Roberts points out, the expectation that the attending list might be more sensitive than the sick list "is not completely realized. The trends in the sick list figures are somewhat clearer and the rise somewhat greater." But since attending-list patients are ten times as numerous as sick-list patients the rates gave what was urgently needed, an index that would provide significant figures over short periods of a week or two in one big ship, or in a small squadron of two or three small ships. Secondly, Fraser Roberts' paper clearly demonstrates the usual difficulty met with by all those who try this kind of co-operative statistical research. This is the problem of getting many medical officers (and others) to fill up forms intelligently and accurately even when they are really trying to be helpful. In addition this return was inaugurated at a most unpropitious time at the end of the war, when the use of ships as transports, the giving of leave to ships' companies, and, last but not least, the great psychological relaxation of tension which inhibited all interest in everything but demobilization also accounted for a large number of attending-list forms which had to be rejected as useless.

This experience, and many others of a similar nature, point a lesson no workers in social medicine can afford to neglect—namely that in research dependent on statistical returns it will generally save time, money, and disappointment to employ a few trained and tactful specialist medical officers or field observers who collect the data exactly what is wanted and why it is wanted. Nevertheless, in spite of these difficulties—indeed, from one aspect, because of them—Fraser Roberts was able to prove that the attending-list return could be made easy and almost foolproof, and that it was the most rapid and reliable method yet devised for enabling the Medical Director-General and his staff to follow at a glance fluctuations in the social health and habitability of the fleets, squadrons, and single ships for which he was responsible. In addition the new return should prove invaluable for testing directly the efficiency of new ventilation, air conditioning, and other schemes for maintaining the health of ships' crews.

Fraser Roberts calls his paper "a contribution to medical climatology." In this context it should be noted that a ship's crew is unique in that its own private physical and social environment is carried around the world with it. Man's success as a species depends not so much on his biological plasticity—his power of adaptation to an ever-changing environment—though that is great enough, but on being the only species that by the use of tools, shelters and clothes has succeeded in adapting every conceivable environment to himself rather than in adapting himself to the environment. This principle should now be applied in the modern warship, which must be adapted to provide a suitable climate for her human complement. This means that ships must be air-conditioned to counteract the cold of the Arctic ocean and the heat of the tropic seas.

## MORBIDITY SURVEYS

In the annual reports of the Registrar-General a hundred years ago Farr produced evidence that the excessive mortality in some areas resulted from unhygienic conditions of life. Since that time changes in living conditions have almost eliminated such diseases as smallpox and typhus and have brought about a steady improvement in mortality figures. In recent years, therefore, studies of mortality have given way to surveys of morbidity. In the first instance studies of the extent and causes of sickness were made in hospital. Hospital reports have always contained figures tabulating in varying detail the causes which led to admission of the patients. It has rarely been possible to relate these patients to the population from which they were drawn, and in addition the reasons for admission to any hospital may change appreciably over a short period. Many of the larger authorities—for example, the London County Council—have published extensive statistics which served rather to indicate the lines along which research might be pursued than to provide answers to specific problems.

Within the last few weeks the Nuffield Provincial Hospitals Trust has published a survey<sup>1</sup> by the Glasgow Health and Sickness Bureau of hospital-treated sickness among the population of Stirlingshire in the 12 months beginning on Oct 1, 1946. This was a pilot study designed as much to find out the difficulties inherent in an investigation of this kind as for its own results. It may serve as a useful guide for further studies of the influence of social factors on the incidence of sickness treated in hospitals. In the past the paucity of data has made the study of the incidence of sickness among the general population almost impossible. Very little was known of minor sickness which caused no incapacity. The frequency of the different causes of illness and the resulting incapacity have been tentatively estimated, however, by inferences drawn from specific inquiries concerning a selected section of the population.

The most recent of these special investigations is that by Dr Cecil Roberts, who has reviewed the sickness experience of Post Office employees over the past 50 years. During this period the staff increased greatly in size. In 1946 three times more men and nine times more women were employed than 50 years earlier. Women had a higher sickness rate than men, on an average each woman was absent for 15.9 days in the year, against 12.3 for men, in 1946. The rate for 1946 was considerably above the rates for the inter-war period, when the differences between the sexes were not so marked. The average number of absences due to sickness was slightly larger for both males and females at ages under 35 than in the older groups, but the average length of absence per illness showed a steady rise with increasing age. There were considerable differences in the sickness rates among various occupational groups and in different regions of the country. Some of the variations over the period were possibly due to administrative policy but the age of the population at risk must be considered an important factor.

<sup>1</sup> *Hospital and Community*, 1. Hospital treated Sickness Amongst the People of Stirlingshire, 1948. Nuffield Provincial Hospitals Trust.  
<sup>2</sup> *Mon. Bull. Min. Hlth.* 1948, 7, 184.

During the recent war it became necessary to determine whether abnormal living conditions, rationing, and other restrictions were affecting the health of the nation. Since there were no data in existence that could be used to find an answer to this question, the Ministry of Health undertook to arrange periodic sickness surveys. Comparisons of the results obtained showed the general trend of sickness, but for a number of reasons the actual sickness incidence may differ from the picture revealed by the survey. The various types of surveys that have been undertaken, the obstacles encountered, and the difficulties inherent in the schemes are discussed by Dr E. R. Bransby in a paper published elsewhere in this issue (p. 678). As a wartime expedient the morbidity surveys gave a reasonably good indication of changes in the incidence of sickness, but it is open to doubt whether under more stable peacetime conditions the results justify the labour and expense of their collection.

Some over-optimistic hopes have been expressed about the value of the information which may be obtained by morbidity surveys. The object of any survey must be more than the mere collection, tabulation, and sub-tabulation of a mass of figures, since this type of investigation can provide little help to either the administrative or the executive authorities. Dr Bransby suggests that the future of social surveys, including morbidity surveys, depends on the testing and developing of techniques. In morbidity surveys there are two primary conditions to be fulfilled before a start is made. The first is that there should be specific questions to be answered, and these questions must be presented in such a form that they can be answered. The second condition is that the data must be sound—advanced mathematical treatment in the analysis cannot make up for inaccurate fact-finding. The present methods of carrying out surveys contain so many potential sources of error that reservations must necessarily be made in attempting to draw conclusions from them.

### SLIGHT ENLARGEMENT OF THE HEART

Cardiac enlargement is one of the most reliable signs of cardiac disease, and when heart failure is present the size of the heart gives some indication of the gravity of the condition. Considerable enlargement can usually be detected clinically, but x-ray examination is needed for the diagnosis of moderate or slight enlargements. Even radiography, however, is not always able to settle the question. There is a considerable range in size in the normal individual depending on height, weight, sex, and shape of chest. In the past there have been many attempts to find a formula for calculating the size of the heart from exact measurements, and these were fully described by Roesler,<sup>1</sup> who considered that the heart size could be determined correctly only by the method of volumetric reconstruction. But even when the exact volume of the heart is known and compared with figures obtained from a study of normal subjects it may still be impossible to say whether or not enlargement is present. Laubry and his colleagues have expressed the generally accepted view—that such methods of mensuration are useless in determining enlargement which cannot be diagnosed by simpler methods.

In a paper published elsewhere in this issue Dr R. Hartley describes an investigation into the causes of slight cardiac enlargement in a series of 18 cases. The method used to determine enlargement was radioscopy performed by more than one experienced observer. Apparent enlargement was found in deformities of the chest, and sternal depression, as described by Evans,<sup>2</sup> is especially likely to give a false impression of enlargement. The importance of actually seeing the patient before giving an interpretation of an x-ray picture is thus obvious. In some of Hartley's cases slight cardiac enlargement was recognized at a time when no cause could be discovered, yet later a murmur of aortic incompetence was found. Though suspected originally, the aortic lesion could not be confirmed even after a most diligent search for the murmur. In such cases there is clearly a use for phonocardiography. Another cause of slight cardiac enlargement without valvular disease or hypertension which might be added to the list given by Hartley is chronic constrictive pericarditis, for though these cases are not numerous their recognition is of great practical importance because of the successful results of operative treatment.

### SURFACE PHAGOCYTOSIS

Workers in the United States have always been to the fore in studying pneumonia experimentally. Methods have been evolved for producing lobar consolidation at will and with regularity, these have thrown much light both on the genesis of the disease and on the mechanisms concerned in recovery from it. In one direction at least the findings have wider implications: they appear to require that we should recast our ideas about the conditions governing phagocytosis. In sulphonamide-treated experimental pneumonia, examination of the lung at different stages makes it clear that phagocytosis is responsible for the destruction of the bacteria. W. Barry Wood and his colleagues<sup>1,2</sup> have shown, first in connexion with pneumococcal pneumonia in rats and more recently to that due to *Bact. friedlander*, that each of these capsulated bacteria, which are supposed to be resistant to phagocytosis unless in the presence of antibody, are in fact actively attacked, ingested, and demonstrably killed by leucocytes before any opsonin can be detected in the blood. They devised an ingenious series of experiments to determine why this phagocytosis occurs in the lung, whereas the same organisms are entirely immune to attack by living leucocytes under ordinary conditions *in vitro*.

That some purely mechanical factor was concerned was suggested by an experiment in which leucocytes and bacteria were introduced into a lung which had been fixed whole and washed free of formalin. Phagocytosis occurred in this environment with or without artificial respiratory movements. Leucocyte-bacteria mixtures were then placed on various surfaces. On glass or cellophane nothing happened, on fragments of boiled tissue of many kinds and on filter paper or cloth phagocytosis occurred. Finally, by using thoroughly washed and dried histological sections of lung the process could be seen taking place in the alveoli. The inert skeleton of lung tissue was placed on a coverslip and the leucocyte-bacteria mixture added, the latter filled the alveoli with a shallow layer of fluid, and the behaviour of its living elements could be studied in a hanging-drop preparation. It could then be seen that leucocytes encountering bacteria away from the alveolar walls passed them by, on the other hand if they happened to pin them against the alveolar wall ingestion followed. The same thing occurred when bacteria were trapped between the surfaces of two leucocytes in contact. The beautiful serial

<sup>1</sup> Clinical Roentgenology of the Cardiovascular System, 1937, Springfield, Ill.  
<sup>2</sup> Radiologie Clinique du Cœur et des Gros Vaisseaux, 1939, Paris.  
<sup>3</sup> Brit. Heart J. 1946, 8, 162.

photographs illustrating the phagocytosis of *Bact friedländer* under these conditions are unmistakable, in their significance. The ingestion of bacteria only when they are immobilized by being trapped between the leucocyte and another surface, whether that of another leucocyte or a fixed tissue cell, has been named "surface phagocytosis". That it occurs in the absence of antibody has been abundantly proved. On the other hand, in the presence of opsonin phagocytosis is independent of this mechanism, bacteria being ingested when in suspension in a fluid medium.

It seems certain that these observations have a wider application, and that phagocytosis anywhere is conditioned by mechanical factors. As these authors point out, one of the reasons why lung abscesses complicating *Bact friedländer* pneumonia cannot be sterilized may well be that in a cavity containing nothing but fluid the physical conditions most favourable to phagocytosis are lost. The same consideration should apply to suppuration and to fluid effusions in general elsewhere. It may well have a bearing on the genesis of diffuse meningitis and on persistence of infections of the urinary tract. It will be interesting to watch the impact of this new idea on the study of inflammation generally.

### KEROSENE POISONING IN CHILDREN

Like all other volatile hydrocarbons kerosene (lamp-oil) is essentially a narcotic, producing cerebral depression and a more or less severe paralysis of the vagus and respiratory centre. It appears, however, that children who recover from the immediate injurious effect of accidentally swallowing kerosene may develop later lesions, both inflammatory and degenerative—inflammatory in the lungs, and degenerative in the myocardium, the liver, the kidneys, and the gastro-intestinal tract.

A recent analysis<sup>1</sup> of 35 cases of accidental kerosene poisoning in children divides them roughly into three groups, according to the predominating incidence of cerebral, pulmonary, and degenerative signs. The cerebral group showed marked drowsiness but very little evidence of lung involvement, and they recovered rapidly. The pulmonary group developed severe pneumonia, and recovered slowly. Children in the degenerative group also had severe pneumonia, but in addition developed signs of cardiac injury, persistent albuminuria with blood cells and casts, and, in some cases, hepato-splenomegaly and occult blood in the stools.

Whether aspiration of kerosene or its absorption from the gastro-intestinal tract is the more important cause of the pulmonary and organic lesions is still a matter of some uncertainty, but animal investigations<sup>2</sup> have indicated that vascular damage resulting from absorption into the blood stream is certainly a factor in both.

In any case the treatment is to remove as soon as possible all traces of kerosene from the gastro-intestinal tract in order to prevent not only further absorption but also further injury to the mucous membranes. In the 35 cases referred to emergency treatment consisted of copious gastric lavage with weak sodium bicarbonate solution, administration of cardiac stimulants, of penicillin to prevent secondary bacterial infection of the lungs, and of dextrose solution and oxygen to reduce the hazard of pulmonary oedema. All these children made a complete recovery, even the degenerative changes proving reversible and leading to no permanent damage.

### PERMANENT INTUBATION OF THE THORACIC AORTA

Fifty years ago the problem of intestinal anastomosis was being thrashed out, with Senn and Murphy as the two advocates of the alternative methods of direct suture or the use of some mechanical contrivance. The universal use to day of suture methods indicates how that problem was settled. Similar questions are now arising in connexion with the anastomosis of blood vessels and, to a lesser extent of hollow ducts such as the ureter and bile ducts. It is as well to view these matters against the broad panorama of surgery as a whole rather than to consider the local problem alone, and there is ample justification for reopening the case for mechanical methods of anastomosis now that more suitable substances are available, such as vitallium tubes and the whole range of plastics. Moreover, there are occasions when it is necessary to bridge a gap which it is not possible to close by direct anastomosis.

Owing to his interest in resection of the aorta for coarctation, Hufnagel<sup>1</sup> has experimented with the permanent intubation of the aorta in dogs. He has reviewed the literature on similar mechanical methods of blood-vessel anastomosis, and much of this is reminiscent of the Murphy-Senn dispute. There are obvious advantages in establishing temporary bridges to maintain circulation, if only for a few days while a collateral circulation is improving, and even if thrombosis occurs early in a proportion of cases. Hufnagel suggests that a new plastic, methyl methacrylate (Lucite), possesses properties which may make it suitable for permanent intubation. It is well tolerated by the tissues, has a high tensile strength, absorbs practically no water, is easily worked, and is inexpensive. It also has the highly desirable property of delaying the coagulation of blood.

The tubes used in this study were machined from blocks or cylinders, and the ends, which had two grooves with an intervening ridge, were carefully tapered. The tubes were 4 cm long, and the walls were 1 mm thick, two sizes were used, 1 cm and 1.3 cm in diameter. The inner aspect was polished to an extremely smooth finish with finest jeweller's rouge.

Fifteen dogs were used in the experiments. One to three centimetres of the thoracic aorta below the left subclavian artery was resected and continuity restored by a tube. The time of aortic occlusion was always under 10 minutes and often no more than 5-6 minutes. Seven of these dogs died as a direct result of the procedure—i.e., from shock or from haemorrhage caused by the ligatures cutting through. Three more died soon after operation (from pneumonia and empyema), but the tube appeared to be working well in each case. Five were killed at times up to 6 months, and again the vascular result was satisfactory. In none of the experiments did thrombosis occur. It is clear that the greatest danger is cutting through of the ligatures, and Hufnagel found that braided silk was the best material.

From the result of these experiments it would appear that no case has been made out for a plastic tube to replace direct anastomosis of the aorta by suture—a method that has proved successful. It is, however, a useful technique to have in reserve should some accident occur to make direct anastomosis impossible. It may have a use in cases in which the aortic atresia is too long to permit resection and direct suture. In man large vessels down to the size of the femoral artery could be intubated by this method. Possibly it could also be used for replacing segments of bile duct or ureter.

## ANNUAL CONGRESS OF PHYSIOTHERAPISTS

### THE NATIONAL HEALTH SERVICE

The Chartered Society of Physiotherapy held its annual congress from Sept 22 to 26 in St Pancras Town Hall. For the first time in the Society's history the congress was an international one, invitations having been sent to physiotherapists' organizations all over the world, a special session was held for a discussion on international collaboration in physiotherapy.

At the opening session, presided over by Dr W S C Copeman, chairman of council, an address on the National Health Service was given by Sir WILLIAM SCOTT DOUGLAS, secretary of the Ministry of Health. Sir William Douglas began by asking his audience to imagine what it was like in countries where there was no planned health service on a national basis. He quoted from a study made by P E P into conditions in the United States, where only about 4% of the population were voluntarily insured for anything approaching full medical care and 75% were without any kind of health insurance at all. The lowest income groups suffered more from ill-health and received less medical care than the other sections of the population. As for the distribution of general practitioners in the States in 1938, in the counties surveyed where the average income per head of population was \$100 or less a year, the number of doctors was 45.6 per 100,000 population whereas in counties where the average income per head was \$600 or over the number was 170 per 100,000. This was in a country wealthy and up to date, and the condition in other countries not so fortunately placed might be imagined.

Dealing with the finance of the national scheme, Sir William said that there was no real connexion between the payments under the national insurance system and the benefits under the National Health Service. The latter was a free service for all, financed principally from rates and taxes, plus a small contribution—some £30,000,000 out of a total cost of the service in the first year of £150,000,000—from the insurance fund.

In the new hospital grouping the disadvantages commonly associated with State control—uniformity, red tape, soullessness of the State machine—had been obviated. He described it as a great act of abnegation whereby the Ministry had surrendered its powers over the hospitals to regional boards and management committees. It was sometimes said that research and State control could not go hand in hand, but that was disproved in his experience at the Ministry of Supply during the war when the best scientific minds in the country carried out a magnificent work of research under Government auspices in connexion with armament, and he could not believe that in the medical world the research would be less fruitful.

The general practitioner service was a universal medical service, open to everyone, with freedom of choice. Private practice was allowed, and the fears of doctors about direction had been overcome. At the moment more than 90% of the public had signed on doctors' lists, and the great majority of doctors had come into the service. On the subject of health centres a report had been received from the British Medical Association and the Ministry had also a committee of its own to consider their organization. The centres would take different forms up and down the country, uniformity was not desired.

The rush for spectacles in the early days of the service was understandable. A recent survey in Wolverhampton had shown that among men over 65 and women over 60, 90% wore spectacles for reading but one-third of them admitted that their glasses were unsatisfactory and one-sixth that they had obtained them from a general store or a travelling salesman or had inherited them from a relative, 36% had had no sight test for five years. The matter would adjust itself in time.

Dealing finally with physiotherapy, the Ministry was fully alive to its importance, particularly when it was regarded as part of a rehabilitation process and the physiotherapist one of a team associated with doctor and surgeon, remedial gymnast and occupational therapist. It was considered that at the beginning of the health service physiotherapy should be associated with hospitals but in the later stage there would have to be a domiciliary service.

### Physiotherapy in Industry

Dr E H CAPEL addressed the congress on physiotherapy in industry. By the end of the war, he said, there were in industry 180 full-time and 900 part-time doctors, with 7,700 nurses, half of whom were State-registered. Since the war ended there had been some reduction in these numbers, but the majority both of doctors and of nurses remained. He could not give the exact number of physiotherapists employed in industry. He had sent out a questionnaire to the medical officers of about 70 large industrial concerns, and of the 64 who had replied, 54 said that physiotherapy was used in their works. The best physiotherapy services were afforded by large engineering firms and by a certain number of food manufacturers and commercial houses. In 48 of the 54 cases radiant heat and infra-red treatments were provided, in 45, ultra violet, in 41, massage, faradism and galvanism were provided by a much smaller number, and 16 provided short wave and three long-wave diathermy. The number of untrained staff in these physiotherapy departments added up to over 200. It appeared that a large part of physiotherapy in industry was given by persons who had had no special training in that subject, usually by nurses who, of course, were mainly occupied with other duties.

Physiotherapy in industrial medicine, Dr Capel continued, enabled many to continue at work who would otherwise be unable to do so because of the difficulties in attending for treatment at hospital. The cases customarily seen at industrial clinics were of injuries and sprains, all sorts of septic and rheumatic conditions (rheumatic conditions being particularly common in coal mines and in iron and steel and some other heavy industries), and another group of cases were those which arose from routine repetition jobs in which the same group of muscles was used all day long. These last cases very often appeared immediately after the worker had resumed his job following upon a short absence. Postural defects which arose in industry benefited by physical exercises. Except in the case of the more trivial accidents it was usual to notify the workman's private doctor and obtain his approval for any course of treatment.

### The Experimental Approach to Physiotherapy

The Founder's Lecture in connexion with the congress was delivered by Professor L J WITTS with Lord Horder in the chair. Professor Wits spoke on the experimental approach to physiotherapy. In this field, he said, they were largely dependent on the scientists for any advances they were going to make. The number of first-class physicists or chemists who would be prepared to work in physical medicine would always be small and the number who could get the correct biological grasp of things would be even smaller. But when these men did enter medicine the help they could give was out of all proportion to their number, and they soon learned to think clinically. The idea must not be allowed to grow that the physicist did the research and the doctor the clinical work, there was a true combination. Professor Wits illustrated his point by describing some research on the application of radiant heat. In one hospital—hospitals, if we came to think of it, he said, were in some ways the most dangerous places in the world—twice within a week semi-conscious patients were burned by the application of a radiant-heat cradle. Instead of blaming the nurse a physicist was called in to ascertain why the cradle was so dangerous and how it could be improved. As a result the application of the cradle was made quite safe and the transmission of heat much more efficient.

The problem of pain, Professor Wits continued, had always attracted some of the best brains in medicine, but it was a curious thing that at the present time there was a shortage of trained clinical investigators for work on rheumatism. One of the reasons why research was not carried out was because patients were segregated in special departments and the problem of chronic rheumatism was not sufficiently brought to the notice of the young man in general medicine. There was always a difficulty in attracting a young man to borderline subjects—and rheumatism was on the borderline of medicine, surgery, physiotherapy, and other disciplines. The only way to get such men was to provide first rate centres of research directed by scientific workers, and one of the encouraging happenings since the war was the way in which these centres were being developed.

Dealing still with the conveyance of heat to the tissues, Professor Witts said it had been ascertained that the transition from a comfortable heat to the sensation of burning occurred quite sharply at 44–45° C, and it had become clear that much more heat could if necessary be put into the tissues without producing burns. The stage was set for a quantitative study of the local and general effects of radiant heat in health and disease. When we get back to the research on pain it will be simpler to begin by studying the effect of physiotherapy on experimental lesions whose nature and extent we know. Lesions of various kinds can be produced with little or no danger in the muscles, joints and ligaments, and experiments can be carried out on well characterized diseases such as gout and rheumatoid arthritis."

Dr W S C COPEMAN in proposing a vote of thanks to the lecturer said that the profession of physiotherapy was entering upon a new era for various reasons, but as a result of Professor Witts' talk he had hope that the science of physiotherapy was entering upon a new era also. Professor Witts had brought the method of what was known as clinical research to bear upon this subject and the results would be of very far-reaching importance.

Other lectures given in the course of the congress included one on rehabilitation of the injured, by Mr H OSMOND-CLARKE, on the management of the arthritic patient by the physiotherapist, by Dr H A BURT, on the role of physiotherapy in obstetrics and gynaecology, by Professor GREEN-ARMYtage, and on the quadriceps in relation to recovery from injuries of the knee joint, by Mr I S SMILLIE.

The congress had its international side. A special meeting was held to discuss international collaboration in physiotherapy, and at another meeting speakers from Germany, Belgium, Norway, Sweden, the United States, and other countries gave brief outlines of the treatment of poliomyelitis as practised by them. Most of them emphasized the importance of warmth to the limbs, and in particular the avoidance of fatigue of the muscles by excessive electrical or other treatment.

At a luncheon held in connexion with the congress, presided over by Lord Horder, Dr COPEMAN said that there were not enough members of the Society to fulfil the needs of the National Health Service Act. The Council had recognized that a certain amount of temporary dilution was inevitable, but it was anxious that the standards of the profession should not permanently be lowered.

## Preparations and Appliances

### GLOVE DRAINS

Dr A HOVNIANIAN, assistant surgeon, Altounyan Hospital, Aleppo, Syria, writes: Owing to the scarcity of rubber tubing during the war I used discarded surgical gloves as drains. I have continued with this practice because of its usefulness. It is also economical. No claim is made to originality, and the only reason for publication is that it may prove useful to those practising at the outposts of civilization who are handicapped by scarcity of materials. Even during times of peace, all torn and mended gloves that are unsafe for operative use are collected,

loose tags of rubber are removed and the ends of the fingers cut. Long gauze strips with infolded ends are tucked into each finger so that they just show at the tips (see illustration). Gloves thus prepared are put singly in special labelled bags and autoclaved. No powdering is used. Favourable sites for drainage are large pus cavities such as subdiaphragmatic, perirenal, or pelvic where after the initial evacuation adhesions are apt to form between the two flattened surfaces of the abscess. In cavities where there are subsidiary pocketings glove drains might be of value, as the fingers of the drain may be spread out by squeezing the glove at the wrist.

## Correspondence

### RMBF Christmas Appeal

SIR,—I appeal once more to members of the medical profession to help those who are dependent on others for extra comforts. The beneficiaries of the Royal Medical Benevolent Fund are in such a case. They are either aged or infirm practitioners, their wives widows, or children, and, through no fault of their own, find themselves in need of help.

I hope that subscribers to the Fund will send donations to provide a little extra cheer at Christmas time and I earnestly beg those who are not subscribers not only to send Christmas gifts but to become regular supporters of the Fund. A special effort to obtain new subscriptions is urgently necessary because certain medical bodies such as the Panel Committees, which used to make generous contributions, have gone out of existence with the National Health Service Act.

Donations and subscriptions, marked 'Christmas Gifts', should be sent to the Secretary of the Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, London SW15, and will be gratefully acknowledged—I am, etc.

WEBB JOHNSON  
President Royal Medical Benevolent Fund

### Medicine in the Commonwealth

SIR,—I should like to add a few words to your comment (Sept 25, p 606) on the latest development in the activities of our Association. I refer to the British Commonwealth Medical Conference and its complement the Empire Medical Bureau. This is a new departure of which the Association has every reason to be proud. It is all to the good to join in promoting a World Medical Organization, but melancholy experience of what has been done, or not done, by ambitious international bodies seems to me to point to the advisability of cultivating assiduously the much more promising family field. For the British Commonwealth is a family affair. During my official career one of our proudest boasts was that wherever the British flag was found, there you would find the BMA. But I never felt very comfortable when I thought of the unbounded hospitality shown to British medical visitors to other parts of the Empire, and the small return we often made for it. The Council has shown great wisdom in setting up the Empire Bureau with an able and enthusiastic director. The Commonwealth Conference is a natural and welcome sequence.

The future historian of the BMA will, I believe, record this development as one of the wisest things the Association has ever done, and in saying this will I hope, give due credit to our Past President, Sir Hugh Lett, who during his term of office did much to bring home to us a larger conception of the services we could render to our branches and affiliated bodies overseas. Those who reuse this country of imperialism might with advantage consider the way in which those members of the family have shown their belief that their membership of the Empire has been to them a benefit and a source of pride. In no sphere has this been shown more happily than in medicine. There is a great opportunity to increase this feeling of solidarity, and our Association has grasped it.—I am etc.

London SW 7

ALFRED COX

### Graduates from the Dominions

SIR,—As a Dominions graduate student who abandoned general practice on Vancouver Island in order to come to Britain for surgical training I want to thank the BMA and to congratulate those responsible for the excellent machinery which exists to help those in my position. My wife and I left Canada with considerable misgivings, having given up a reasonably lucrative post to come to austere Britain. Our experience since arrival has removed all our fears. The British Medical Bureau found me a satisfactory interim surgical post while waiting for the Royal College of Surgeons course to commence. The Empire Medical Advisory Bureau has given me much good advice concerning postgraduate plans and at the moment the same

body is helping me to find a London flat. The British Post-graduate Medical Federation and other groups have been similarly helpful. I regard medical experience here as of enormous value apart from the obvious benefits in training. At a time when international unpleasantness is not a remote possibility, the exchange of graduate students would appear a very real way in which Empire co-operation can be furthered. A stream of students in both directions would perhaps be of value to all concerned—I am, etc.,

Hove Sussex

DOUGLAS FINDLAY

### Trilene as an Analgesic

SIR—As I was chiefly responsible for the introduction of purified trichlorethylene as an anaesthetic and analgesic in 1941, may I be allowed to comment very briefly on Mr F Neon Reynolds's plea (Sept 25, p 620) for its domiciliary use by midwives? It is true that 'trilene' is a most effective analgesic and can be given with a simple and portable inhaler, but when it comes to legalizing its use by midwives all sorts of complications arise. The Council of the Association of Anaesthetists of Great Britain and Ireland has had the matter under active consideration for some time and the two research fellows of the association have been engaged on whole-time work on the subject. A brief interim report will be found in the current issue of *Anaesthesia* and it is hoped to include a more detailed account of the important findings in the next number. I would suggest that those interested should peruse these reports, and they will then realize the complex problems which have still to be solved before the ideal 'foolproof' obstetrical analgesic can be provided—I am, etc.,

St Albans Herts

C LANGTON HEWER

SIR—Mr F Neon Reynolds's letter (Sept 25, p 620) brings out the point that some improvement in the means of affording relief of pain during childbirth supervised by midwives is long overdue. The solution of the problem, however, is not so simple as he hints. Two outstanding defects in the "trilene" inhalers at present available for obstetrical analgesia are that the strength of vapour delivered varies both with room temperature and with the depth of respiration of the patient. Also the susceptibility of the individual patient to anaesthetic vapours has to be borne in mind.

There is no doubt that several inhalers give adequate relief of pain in a high percentage of cases, particularly where intelligent supervision is exercised. Nevertheless, a combination of circumstances can arise in which an unduly high concentration of vapour is breathed by a susceptible patient, and then the stage is well set for accidents which the limited training of many midwives in the case of the unconscious patient leaves them incompetent to deal with. Reasonable risks must be taken but it would be hard to justify an occasional maternal or foetal misadventure with apparatus so obviously capable of improvement. If the present inhalers are modified to be safe in all cases they will be practically useless in the great majority.

Work is in hand at more than one centre to construct analgesia inhalers which will be independent of depth of respiration and in which a simple adjustment can be made for different room temperatures—in short a simplified version of a successful chloroform inhaler specially designed for paratroops during the war—I am, etc.,

Oxford

R R MACINTOSH

### Fibrositis

SIR—The letter of Dr M G Good (Sept 25, p 617) adds very little clarity to the article of Dr James Cynax (July 31, p 251). Dr Good's hypothesis that the myalgic spots are due to abnormal vasodilatation by stimulation of the vagus (vagotonia) which would lead to a deficient circulation and anoxia, is, to say the least, somewhat difficult of comprehension.

The following are some of the many questions that come to my mind on reading his letter: (1) Does vasodilatation produce ischaemia? (2) How may one ask, is the vagus stimulated in these conditions, and, even then, how can it produce myalgic spots in areas so distant from its own areas of distribution? (3) Does Dr Good suggest that the vagus takes part

in the innervation of the latissimus dorsi, or, for that matter of the gluteus maximus—two muscles which may appear to the patient to be the sites of pain? To do so is to suggest that since we first studied the first principles of anatomy we have developed—perhaps tragically—some phylogenetic changes in our 'constitutions'—I am, etc.,

London N 4

I H MILNER

SIR—I must join forces with Dr M G Good (Sept 25 p 617) in the matter of local vasomotor disequilibrium as being the most certain cause of this tedious and extremely painful condition. One can state with some certainty that the aetiology covers almost all forms of the disease in well-nigh any part of, at least the large muscles. Those who have their own experience realize that abuse, disuse, and trauma will bring an attack. Surely it is reasonable to suggest that, as Dr Good has said, ischaemia is the prime cause. We all know of splendid athletes who gave up their sports to sit on an office stool and become what are said to be muscle-bound. If that is not fibrositis, what is it?

I agree entirely with Dr Good in his repudiation of the suggestion that primary fibrositis is an imaginary disease. Anxiety may bring on an attack or vice versa.

In the Tropics chills and dampness are very well known causes, and the complaint seems to be more severe, motor cycling is really dangerous in those who are affected—I am etc.

A HENRY PRICE

### Suppression and Treatment of Malaria

SIR—I have read with very great interest the reply given under the above heading ("Any Questions?", Aug 21, p 407) to a query regarding the value of paludrine, mepaerine, and quinine respectively, for the suppression and treatment of malaria. But, while I agree most heartily with the statement,

"For suppression, the drug chosen must be taken daily," I am convinced that the reference to quinine and blackwater fever needs considerable qualification.

When I was sent by the Indian Government over forty years ago to investigate blackwater fever in the Jalpaiguri Duars of Northern Bengal, we doctors in India used often to wish that we had remedies for other dangerous diseases one-half as effective as quinine was known to be for malaria. At that time I was not the least afraid of malaria personally, because seven years' work in a hyperendemic area of Assam had taught me how to protect myself by the systematic use of quinine. I used to take a 5 grain sugar-coated tablet of quinine sulphate every day, and if I developed any sort of symptom whatsoever, such as a headache, sore throat, indigestion, constipation or looseness of the bowels, instead of stopping the quinine I promptly doubled or trebled the dose for a few days. Before adopting this regimen I had suffered repeated attacks both of benign tertian and malignant tertian malaria so much so that on one occasion I nearly threw up my Assam appointment. But from the time I began to take quinine in the manner described I kept extraordinarily free of malaria, in an area where the spleen and parasite indices exceeded 90%.

At that time little was known regarding the origin of blackwater fever, which was thought by some authorities to be due to a special parasite. Schuffner, for example, had reported seeing bodies resembling spirochaetes in the blood of blackwater-fever patients. I had failed to confirm Schuffner's findings in a few cases examined in Assam, and I must confess that when I went to the Duars where many fatal cases of blackwater fever had recently caused nearly a panic among the planters, I did so rather in fear and trembling.

After I had been at work in the Duars for a few months Major S R (now Sir Rickard) Christophers, I.M.S., joined me and we continued our investigations for the best part of two years eventually publishing two reports—one on malaria in the Duars and the other on blackwater fever. In the latter report, on page 173 we state the following conclusions:

"Blackwater fever results from a condition induced by repeated attacks or infections by malaria. It is precipitated by an acute attack of malaria, especially when under certain conditions this is associated with the administration of quinine. Quinine itself is innocuous and cannot have such an effect on a subject not pre-

pared. The consistent use of the remedy (quinine) by a community may even diminish the incidence of blackwater fever by reducing the liability to malarial infection.

The value of quinine for suppressing attacks of malaria and diminishing the incidence of blackwater fever is referred to again on page 177 of our report on blackwater fever, where, after mentioning four examples quoted by Decker in which the adoption of quinine prophylaxis against malaria was followed in each case by a reduced prevalence of blackwater fever, we go on to remark

'Quinine prophylaxis, it is obvious, to be of any use must be effectively pushed. In the Duars already a large proportion of the European population has taken to the systematic use of quinine. The result has so far been not only a much reduced amount of malaria amongst those taking the precaution, but a very small number of cases of blackwater fever in this community. Only three cases which occurred among Europeans during the past twelve months were among those who professed not to believe in quinine and only took it when they felt unwell.'

There had in fact been a startling reduction in the number of cases of blackwater fever after the commencement of the inquiry in May, 1907 *pari passu* with the progressive adoption by the planting community of a daily dose of quinine as a protection against malaria. When I came to leave the Duars in 1909 to take up the investigation of malaria in other parts of India I was not only confirmed in my former opinion regarding the value of quinine as a safeguard against malaria, but over and above this I had become convinced that a small daily dose of quinine was an even more certain preventive of an attack of blackwater fever than it was of an attack of clinical malaria. My experience during the next five years only strengthened these views and at the outbreak of war in 1914 led me to volunteer for active medical service on any malarious front specifying for choice any area where blackwater fever was known to be endemic.

It will be seen from the foregoing that my experience affords no support to the statement contained in 'Any Questions?' which inspired this letter to the effect that 'If the infection is due to *P. falciparum* or if *P. falciparum* is the prevailing parasite in the area quinine must be avoided both in treatment and in suppression because of the danger of inducing blackwater fever'. On the contrary quinine can safely be used in the circumstances stated if it is used in daily doses for the suppression of malaria. The same rule appears to hold good for mepacrine. Neither quinine nor mepacrine should be used *intermittently* in blackwater-fever areas if dangerous side effects are to be avoided. T. E. Wilson (*Med. J. Aust.* 1943, 2, 414) reports two cases of blackwater fever following mepacrine in men who had intermittent treatment for repeated attacks of malignant tertian malaria. He considers blackwater fever to be consequent upon a sudden dose of antimalarial drugs after a long intermission. 'The onset of blackwater fever immediately after use of mepacrine suggests that this disease is not due to a hypersensitivity to quinine itself, but rather to a by-product liberated from the parasites themselves by an antimalarial drug.'

The moral appears to be that whatever the drug chosen for the suppression of malaria—whether it be quinine or mepacrine and quite probably paludrine also—it would be wiser to take it daily rather than intermittently—I am, etc.,

Wallington Surrey

CHAS. A. BENTLEY

### Analgesia by Sympathetic Block

SIR—Mr. Albert Davis's article (Sept. 25, p. 585) prompts me to report a few cases of the use of 'proctocaine' in sympathetic block.

A man aged 68 feeble and suffering from a bluish, cold, and painful hand following an injury to the thumb, had 10 ml. proctocaine introduced at the level of the 1st thoracic vertebra. This caused a fairly complete measure of relief, lasting at least four months.

A woman aged 59 had a pressure ulcer on the foot which showed no signs of healing. 10 ml. proctocaine at the 2nd lumbar vertebra crabbled the ulcer to heel.

A woman, aged 61 with an old standing hydronephrosis of slight degree, but causing pain had 10 ml. injected at the 11th thoracic vertebra. This removed the pain for at least a month.

A woman aged 50, had thrombosis of the left popliteal artery, left foot colder than its fellow to touch, cramp in calf on walking 100

yards. 10 ml. proctocaine was injected at the level of 2nd lumbar vertebra. Now six weeks later, the foot is still noticeably warmer than the other and she can walk two miles without pain.

I was prompted to try this method by reading the book by Mandl, through the knowledge that Kenny had already safely used proctocaine in the sacral canal, and witnessing Mr. Haxton's demonstration of the use of a carbolic solution. Many patients requiring relief from pain are old or in poor general health, it may be that a few injections a year may make their lives more tolerable. In cases of popliteal thrombosis it is probable that immediate sympathetic block by proctocaine (until something more efficient is discovered) is the treatment of choice—I am, etc.,

OWEN WILSON

### Medicine as a Planned Economy

SIR—Dr. Edward B. Hendry (Sept. 18, p. 567) draws attention to a depressing trend of modern medicine—the use of the laboratory instead of clinical judgment to make the diagnosis and assess the patient's progress. Apart from overloading the laboratory with unnecessary work so that important tests cannot be done or may be done inaccurately, there are other and equally disturbing features.

The first of these is a tendency to regard the patient not as a man but as a factory of blood counts or of interesting x-rays. The day is not far distant, if indeed it is not already with us, when the 'clinician' on his morning round will not observe the patient but look at the report on his blood cholesterol. The second of these features is to be found in the articles in the medical press and in the accounts of disease given in the textbooks. More and more the patient is forgotten in a welter of urine and blood analyses, x-rays, and electrocardiograms, for all of which the description may well be weighed in the balance and found wanting.

Compare any modern description of pernicious anaemia with Addison's original account.<sup>1</sup> To judge from their writings our modern haematologists pay scant attention to the patient. All too often the reader finds that the description of the cases consists of a series of dates against which are written blood and marrow counts, and he is left with a nightmare picture of large cells, small cells, cells with big nuclei, cells with little nuclei and cells with no nuclei at all. From such descriptions he may derive a little knowledge, somewhat less help in his own recognition of the disease, and no pleasure at all. Let the reader turn to Addison. There he will find a word picture that will live in his memory, enable him, supposing he had never seen the condition, to recognize it when he met it later and give him the immeasurable pleasure that only good descriptive prose can bestow.

I have chosen pernicious anaemia to illustrate my point not for poverty of other examples—Bright gives a better and more helpful account of nephritis, Parry and Graves of thyrotoxicosis, and Heberden and John Hunter of coronary thrombosis and angina than any of our contemporaries and other examples abound—but because it and other anaemias are at present much discussed in the medical press and form examples *par excellence* of the poverty of our descriptive writing compared with that of our forefathers and of the use of the laboratory to the almost complete exclusion of the clinical picture. Let us then return to clinical observation, to the use of good, clear English to describe what we see, and to more consideration of the needs and feelings of the patient, or our successors will say of us that our hands like the base Indian 'threw a pearl away richer than all his tribe'—I am, etc.,

SIR—You reprint (Sept. 25, p. 616) the translation of the oath made by Jones in his scholarly work *The Doctor's Oath* (1924). This translation differs very slightly from that given by him a year earlier in the Loeb Classical Library (e.g., the 1924 work gives 'obedience to the physicians' Law but to none other, whereas the better version is 'who have

# An advance in Penicillin therapy . . .

## 'AVLOPROCIL'

### Procaine Penicillin Oily Injection

'Avloprocil' contains the procaine-salt of Crystalline Penicillin in oily suspension and offers important advantages to both doctor and patient —

- Therapeutic blood levels of penicillin maintained for at least 24 hours
- Effective penicillin therapy achieved with a *single daily injection*
- Administration comparatively free from irritation and pain

10 c.c. vials (300,000 units of penicillin per c.c.) Singly and in boxes of 5

#### A SUMMARY OF THE ADVANTAGES OF STREPH

- (1) Non-selective
- (2) Activity is maintained in the presence of proteins
- (3) Non-necrotic, non-toxic, non-staining
- (4) Clear solutions with water, normal saline, and alcohol
- (5) Powerful deodorant
- (6) Pleasant odour
- (7) Powerful detergent and compatible with soap
- (8) STREPH is approximately three times as effective as Liq. Chloroxylenol or lysol

For these reasons STREPH is the ideal antiseptic for medical, surgical and obstetrical use.

## 'TUAMINE SULPHATE'

### 2-Aminoheptane Sulphate

Solution 'Tuamine Sulphate,' when applied intranasally, produces long-lasting, uniform shrinkage of the nasal mucous membrane without stimulating the central nervous system. There is no secondary vasodilatation and no impairment of ciliary motility. Repeated applications do not produce tolerance. Solution 71 'Tuamine Sulphate' 1 per cent is available in bottles of one and sixteen fluid ounces.

VITAMIN FOOD**

TO the physician requiring a product which incorporates important vitamins in a form acceptable to every patient Vimaltol presents special advantages

Vimaltol is made from specially prepared malt extract of high protein content yeast—one of the richest sources of vitamin B,—and Halibut Liver Oil an important source of vitamins A and D. It is also fortified with additional vitamins and mineral salts and is deliciously flavoured with orange juice

Vimaltol is thus an important aid in the treatment of the many abnormal conditions resulting from the deficiency of one or more of the essential vitamins in the average everyday dietary

The routine use of Vimaltol helps normal development of the growing organism and the maintenance of correct metabolism while raising the general resistance against infection

Vimaltol has thus a very wide application in general practice for patients of all ages. It can be prescribed with advantage at all seasons

taken the physician's oath, but to nobody else", the former would appear to be a mistranslation since οὐδεὶς is not an adjective) Your statement that the Oath is reproduced in very few histories of medicine and the somewhat inadequate comments on the reproduction in the most recent history (by Castiglioni, translated by Krumbhaar, second edition, 1947) prompt me to call attention to the important text, translation, and interpretation of Edelstein (*Suppl No 1 to Bull Hist Med* 1943) in which it is convincingly shown that the Oath is a Pythagorean manifesto of the fourth century B.C., and not the expression of an absolute standard of medical comfort.

The Pythagoreans believed primarily in the importance of dietetics, it is a pity therefore that the translation you quote gives "I will use treatment to help the sick instead of, I will use dietetic measures (δαιταγωγία)". They believed less in the efficacy of drugs and least of all in surgery (Would we had a few more Pythagoreans to-day) This, Edelstein points out, explains the difficult passage about cutting for the stone. The translation you give has the weak and almost meaningless word "either" for the strong οὐδὲ μὴν. Surely the obvious translation is the alternative Jones gives and Edelstein adopts.

"I will not use the knife, not even on sufferers from the stone" Certain scholars, perhaps thinking surgery should have a more important place, have made the passage refer solely to castration. Jones and Edelstein decisively reject this, and it would not be worth mentioning had not Castiglioni (*loc cit*) quoted in this vein what he calls Nittis's new interpretation (which was hesitantly suggested by Littré over a hundred years ago).

The Oath is a remarkable document showing a very high ethical standard. Whether the Pythagorean physician who composed it was right in his views on abortion, euthanasia, homosexual practices, and the revealing of confidential information derived from patients (forbidden by him but required under certain circumstances by our law), will no doubt be decided by the World Medical Association if it drafts a new Oath for the highest profession. We should all no doubt like an Oath of some sort but if we follow the Pythagorean manifesto too closely we may have to swear to treat the sons (and daughters) of Ministers of Health as equal to our brothers (and sisters) and to teach them without fee—I am etc.

H. M. SINCLAIR

### Breast-feeding

SIR,—Having read with interest Dr Enid L. Hughes's "Study on Breast feeding in a Mining Town" (Sept 25, p 597), I feel it may be helpful to state some of my own experiences which may be factors in early weaning. Having worked as a G.P. in an industrial practice my impression like Dr Hughes's, is that in very many cases the grandmother was the major single factor and easy access to a clinic another. On the other hand I found that many mothers readily responded to enthusiasm and interest shown by the doctor.

As a mother I should like to point out some of the difficulties that meet with little understanding and could be easily remedied by an interested adviser.

1 *The Cracked Nipple*—Both my nipples were badly cracked a few days after the birth of my first child. The attitude of the hospital nursing staff seemed to be "you are making a lot of fuss about nothing." When I returned home, nobody had any intelligent advice to offer other than to wean the baby. Finally a friend suggested superficial x-ray therapy for the nipples. This enabled me to feed painlessly from one breast, and to express the other by hand three times a day and give the expressed milk by bottle. Both breasts eventually healed. But it is very much better to take the baby off the affected breast for a few days immediately the crack appears and before its base becomes indurated. A pump must not be used, but the breast should be manually expressed at each feed, and the milk given to the baby after the healthy breast.

2 In some hospitals it is the rule to give one breast only at each feed. When the milk supply is only just sufficient, this practice tends to diminish it still further. Mothers should be told that if there is any sign of decrease they should feed from both breasts at each feed.

3 When there is any decline in the milk supply expressing the last few drops from both breasts after each feed seems to help increase milk secretion.

4 Most patients whose milk supply is poor tend to "save up" and give alternate breast and bottle feeds. It is sometimes difficult to convince them that the supply increases with the demand, and that

therefore both breasts should be given at each feed and followed if necessary by a bottle. I have often found that if the mother understood and followed this practice complete breast-feeding was soon re-established.

And, lastly, encouragement by the doctor and nurse, and praise of the baby's condition, are very important indeed. I firmly believe that a more personal approach to many mothers would substantially decrease the incidence of early weaning.

—I am, etc.,

Sheffield 6

ELENA ZADIK

SIR,—I would like to suggest that one can throw some light on the interesting figures given by Dr Enid L. Hughes (Sept. 25, p 597) on early weaning at Newbiggin by comparing them with a very different series, rejecting as causes what is common to both sets of circumstances and listing the differences all of which will be in some degree possible explanations. Here, for instance, are Dr Hughes's figures (all reduced to percentages of the total number of cases) compared with 100 consecutive cases in general practice in York.

#### Dr Hughes's Series

#### My Series

29	weaned by two weeks	4
39.5	total weaned by four weeks	21
19.5	weaned between one and three months	12
41	on the breast after three months	67

These figures are so different that factors equally characteristic of the two environments can be ruled out as explanations of the Newbiggin figures. These factors are overcrowding (including exaggerated modesty and interfering mother-in-law) fashion and unwillingness to be tied. Neither milieu is rural. There remain the heavy work of the fisherwives and the high incidence of shift work in a heavy industry—represented at York only by a much smaller percentage of operative railway workers. Finally, there is a difference between the two series which I am inclined to think very important because it affects the whole of the statistical picture—the difference between discontinuity and continuity of treatment. These York cases are closely supervised by the same person from the reporting of pregnancy to the establishment of mixed feeding.

It is striking that Dr Hughes's article says not one word about antenatal treatment of the Newbiggin mothers for education for breast-feeding is undoubtedly needed in these days should begin at the first antenatal examination, and is best done by the person who is to supervise the rearing of the infant. Notice next that under "Reasons for Weaning" Dr Hughes is forced to give the reason advanced by the mother after the event, while I give the reason according to my own observations at the time.

As a first consequence the cases where no reason was definitely established are Newbiggin 14% mine 0%. As a second consequence I am in a position, and Dr Hughes is not, to divide the weanings unhesitatingly into those that were inevitable and those that were not. Of the four weanings before two weeks all were inevitable: two for infantile nipples, and two for illness of the mothers. Of the following 17, seven were again inevitable, the other 10 classed in my records as deliberate. It is obvious that Dr Hughes is severely handicapped in drawing her picture of Newbiggin mothers by the impossibility of making this distinction and this impossibility arises from the discontinuity of the medical organization.

The very first cause of weaning to be considered in any rational survey is genuine failure of lactation. I report four cases. It is unlikely that this factor is very variable in the human species, and probably Newbiggin has about 4% of failures somewhere. Owing to the discontinuity of the medical organization Dr Hughes has to confess that she cannot say where they are, they may be among the unexplained cases but they may equally be due to difficulties with the baby at the breast, for which the figures are Newbiggin 23%, mine 0%. These difficulties tend to be distributed under other headings when one is able to observe them on the spot.

Finally, I am quite unable to agree with Dr Hughes that her analyses are likely to be veracious because they are obtained early. I consider them to be obtained very late. My experience is that at three to four weeks it is already very hard to reconstruct the history of an infant's feeding. Even when the mother is entirely honest one can discover only what has

led to her worth noticing. In short when Dr Hughes  
out in the fourth week to discover why the babies are  
earned she has the main answer already in her possession. It  
is because she cannot start to investigate until the fourth week.  
—I am etc,  
York

F CHARLOTTE NAISH

### Teaching Occupational Medicine

SIR—In your account of the International Congress on Industrial Medicine (Sept 25, p 613) I have been wrongly quoted as saying that what was needed in teaching [occupational medicine] was fewer general principles and more detail. I did, in fact, suggest the exact opposite—that is more general principles and less detail. Occupational medicine is now being practised in a variety of occupational groups, not only in factories and mines but in commercial and transport undertakings, catering establishments, and even universities. Courses must therefore be designed to equip men and women for the practice of preventive medicine among these different occupational groups. It seems that this can only be done by teaching general principles. An elementary knowledge of such subjects as statistical methods, recording and analysis of morbidity, the influence of working environment on physical and mental health, the placement of the sick and disabled, are of far more value to the future industrial medical officer than a detailed knowledge of industrial health legislation to which reference can be made when necessary, or of the toxicology of a hundred and one metals and chemical compounds which many I.M.O.s will never see. If these courses are designed to teach the principles of preventive medicine it will be possible to have many lectures, visits and demonstrations common to both D.P.H. and D.I.H. courses and thus give teachers more time for research and the preparation of better lectures and less chance of becoming hacks—I am, etc,

Manchester

RICHARD SCHILLING

### Artificial Insemination

SIR—My attention has been drawn to the letter from the Secretary of the Medical Defence Union in your issue of Sept 11 (p 530). Mr Justice Vaisey is of course precluded by his judicial office from writing to the Press, but I have no reason to doubt that he would agree with the comment that I feel obliged to make.

I am surprised that the Secretary of the Medical Defence Union should take the view that a document "specially prepared and issued by the Medical Defence Union for the guidance of medical practitioners" should only be criticized with preliminary notice. I can assure him that there was no confusion in our minds between the Union's memorandum and the article in the *British Medical Journal* to which he refers.

It remains, in my view, true to describe as "superficial" a document which does not refer to the grave risk, approximating to a certainty that one or other or both of the spouses will make a false declaration of parentage and incur liability to penal servitude. It is in my view, grossly misleading to circulate for use a form such as the first of those annexed to the memorandum containing dressed up in quasi legal verbiage, an assurance which no one properly alive to what he was doing could either give or accept. This point is expressly made on page 40 of the Commission's Report, and I do not understand Dr Forbes' statement that no indication is given of the reason for our description of the memorandum—I am, etc,

Magdalene College Cambridge

HENRY WILLINK

## POINTS FROM LETTERS

### Artificial Insemination

We publish below points from a number of replies to Dr Norman Haire's letter (Sept 25, p 621).

Dr S J G SPENCER (Oxford) writes: The basic distinction, which Dr Haire seems to have missed, lies between ecclesiastical laws on the one hand like the obligations to receive Holy Communion regularly and fast during Lent which a Church can rightly enjoin only upon its flock, as Dr Haire correctly implies, and on the other hand ethical precepts which a Church submits as a body of experience in moral principles to the moral conscience of all men, its

members and its non members; for their universal acceptance and adoption. It believes such universal ethical precepts to include laws derived intrinsically from the nature given by God to man. For instance, it considers the prohibitions against murder and theft to be derived from man's natural right to life and property, British criminal legislation has of course already embraced these two prohibitions. Now, it is manifest that if a Church impugns all or some facets of artificial insemination, whether rightly or wrongly, it does so not because they offend against its esoteric rules but because they break laws which, in its estimation, are derived inexorably from man's nature and are therefore universally applicable. Such laws as the need to abstain from onanism and to procreate only through one's spouse. Such a Church must therefore inevitably submit to the moral conscience of mankind the necessity for the universal outlawing of these contrary practices by all possible means, including that of criminal legislation.

Dr G L RUSSELL (London, W1) writes: Dr Norman Haire describes the recommendation of the Archbishop of Canterbury's Commission on Artificial Insemination that "early consideration should be given to the framing of legislation to make the practice a criminal offence as 'monstrous impertinence'." And he makes lavish use of the terms 'totalitarian', 'Nazi', 'Fascist', 'Communist' to support his thesis. I entirely agree with him that it would be intolerable if the Church should attempt to legislate for those who do not belong to it, but no one proposes this. What is proposed is that those who have not only the power but the duty to legislate—that is, Parliament—should exercise that power, and perform that duty, in a matter which this Commission believed to concern all citizens not only members of the Church. Dr Haire seems to have forgotten in his indignation against totalitarianism, that democracy is "government by discussion"—a continuous public debate to which every citizen, and every group, has the right to contribute.

Dr F S SINKER (Leamington Spa) writes: It is the duty of the Church to proclaim, among other things, the Christian ethic, not solely to its own practising adherents but to society as a whole. "whether they will hear or whether they will forbear." That is part of its witness. It knows, and has good reason to know, that medical procedures undertaken without any reference to moral and spiritual values are not fully competent, nor are their long term results conducive to a genuine and lasting rehabilitation of the patient. In the recent statement "Medicine and the Church," approved and published by the B.M.A. Council, occurs this passage: "Moral aspects in the cause, treatment, and prevention of disease cannot be overlooked, and in this field also it is desirable that there should be fuller co-operation. Medicine and the Church working together should encourage a dynamic philosophy of health which would enable every citizen to find a way of life based on moral principle and on a sound knowledge of the factors which promote health and well-being." Here is a clear recognition of the value of any effort officially inspired by the Church to give guidance in those aspects of moral behaviour with which medicine may be concerned, but upon which medicine as such is not competent to express an opinion. There are many of us who regard the annotation on "Artificial Insemination" (Sept 11, p 523) as a most able and fair summary of the value of the report of the Archbishop's Commission, and a well-deserved tribute to its distinguished members. "This Report is bound to stand, as the writer says, 'for a long time to come as an outstandingly able summary of this complicated question'."

Dr CLAUD C M WATSON (Edinburgh) writes: I agree with Dr Norman Haire in that it would be preposterous to make artificial insemination a criminal offence. On the other hand, I think he condemns the Church rather too harshly. I noticed one suggestion in the Commission's Report that I think ought to be strongly challenged, and that was that A.I.D. was "adulterous." Surely the essence of adultery is that illicit sexual intercourse must occur. Not by any stretch of imagination could artificial insemination be regarded as such. My personal opinion is that if a husband has been found to be permanently sterile it is rather hard to prohibit the wife from having a child of her own if, as many such wives are, she is desperately keen to have one.

Dr J HOUSTON PORTER (London, W2) writes: The extraordinary letter of Dr Norman Haire makes such exaggerated and extravagant accusations against "the Churches" that few of its thinking men and women to whom he refers will be misled by it. To suggest that the much vilified Churches, all of which are deeply deploring their present loss of membership and influence could or ever would exercise totalitarian tyranny over the community at large is merely ridiculous. The Archbishop's recommendation which has provoked such an explosive reaction from Dr Haire is simply that consideration should be given to the framing of legislation not by Convocation or any ecclesiastical body but by the people's representatives in the House of Commons.

## Obituary

Mr VIVIAN JOHNSON MORCOM TAYLOR, who was orthopaedic surgeon to the Mansfield General Hospital and the Chesterfield Royal Hospital, died suddenly at his home in Chesterfield on Sept 12. Educated at Kingswood School, Bath, and Liverpool University, he graduated in 1927, and took the MCh in 1930 and the Edinburgh FRCS in 1931. After holding a number of resident appointments he became surgeon-in charge of the Lurgan Infirmary in Northern Ireland, and was later assistant surgeon to Harlow Wood Orthopaedic Hospital. Mr Taylor was appointed orthopaedic surgeon to the Mansfield General Hospital in 1941, and to the Chesterfield Royal Hospital in 1944. A surgeon of marked ability, his opinion was widely sought in the districts in which he worked. He combined an enthusiasm for his specialty with a flair for organization, and at the time of his death he was engaged in reorganizing the orthopaedic services for the Chesterfield district. For many years he had suffered from a severe form of asthma, so that he was more often than not working under difficulties. He fought his distressing complaint with great courage, and would never admit his disabilities even to his friends. In the end it proved more than he could withstand and his premature death at the age of 44 was due to this condition. A charming personality and a man of great integrity he will be missed by many. He leaves a widow, a son, and a daughter.—F J M

Dr CHARLES COWAN MCCALLUM died at his home in Middlesbrough on Sept 16, at the age of 50. A native of Glasgow, he graduated there in 1924, and took the Edinburgh FRCS in 1934. He was first of all a house-surgeon and subsequently honorary surgeon at the North Ormesby Hospital.

Dr I R writes. By the death of Charles McCallum the profession in Middlesbrough has been robbed of one of its most respected and well loved members. Both in his hospital and in private practice he was endeared to professional colleagues and patients alike by an unassuming charm and sympathetic understanding, nothing was ever too great a trouble for him to do, though for him it often meant working to a degree which would have been too much for many a younger man. A surgeon of considerable competence, it was perhaps in his own practice, and particularly in dealing with children, whose confidence and friendship he never failed to gain, that he was at his best. This was surely a reflection of his own ideally happy home life, as those of us who had the privilege of knowing him and his family well can testify. Our loss is great, but theirs is immeasurably the greater.

Dr WILLIAM STEWART who died at Sleights, Yorkshire on Sept 16 at the age of 67, had been in practice in Southampton for over thirty years until he retired two years ago. A native of New Zealand, he graduated MB ChB at Edinburgh in 1911. After a period as a hospital resident and a short assistantship in Yorkshire he came to Southampton and settled in general practice there in 1914. During the 1914-18 war he served in the R.A.M.C. at Netley, his general health, which was never robust, precluding him from service overseas. Then followed a period of study at the Central London Throat, Nose, and Ear Hospital where he became registrar. He then started in specialist practice, and in 1922 took charge of the ear, nose, and throat departments of the Royal South Hants and Southampton Hospital. He resigned this appointment in 1934 and became a consulting surgeon. During this time Dr Stewart had also acted for various periods as surgeon in charge of the ear, nose, and throat departments at the Royal Isle of Wight County Hospital and at the Southampton Children's Hospital. Professionally he had a keen clinical sense and a particularly clear conception of the essentials of his specialty qualities which made his teaching of junior colleagues particularly helpful. His opinion was widely sought and by patients and colleagues alike he was held in high esteem. For many years an active member of the B.M.A. Dr Stewart was elected president of the Southern Branch in 1931. He also served as president of the Southampton Medical Society and during the recent war gave invaluable service as chairman of the Southampton Medical War Committee. His death is felt as a personal loss by a large number of old patients and by a wide circle of friends, and their sympathy will be extended to his widow.—N W M

Dr ALFRED WILSON DANIEL died on Sept 17 at the age of 75 some weeks after undergoing an operation. He was educated at Lancing College and Emmanuel College, Cambridge. After taking his M.A., he qualified MRCS,

L.R.C.P. as a student of St Thomas's Hospital in 1898, and graduated M.B., B.Ch. a year later. Soon after qualifying he joined the staff of the South-West Fever Hospital, and while there, in 1902, obtained the M.D. of Cambridge University. The same year he entered the service of the London County Council and joined the staff of Hanwell (now St Bernard's) Mental Hospital, where he spent the rest of his medical career. Having passed successively through the lower grades he was finally appointed medical superintendent in 1917, and in 1936 he retired. Dr Daniel was quiet and unassuming in manner and disliked ostentation and display. Under this quiet exterior he was very kind-hearted and generous, and many of his patients, colleagues, and friends have had personal experience of these qualities. At all times he had an unflinching sense of humour of a pawky kind which never failed to be most apt. In his work his greatest interest always lay with the patients among whom he spent countless hours so that he knew them all by name and in most cases remembered some facts of their history, a marvellous feat when dealing with more than 2,500 patients. How often did a medical officer who was in charge of a group of wards find that, when a case was being discussed at the morning conference, his chief knew so much more about the history of the case than he did himself. Dr Daniel believed that the only way of really learning about mental illness was to spend as much time as possible in the wards with the patients, and the wisdom of this belief was proved by his own great clinical insight and acumen. His unflinching interest in his patients and also in his staff led to his being held by them in great esteem, and his retiring was felt as a great loss by all. Apart from his work he excelled at golf and for many years was rated scratch. During his retirement he played a daily round as long as his health permitted, and his carefree attitude towards the game made him a delightful opponent as well as a doughty one. In his passing, psychiatry has lost someone who at all times lived up to the highest ideals of this exacting branch of medicine. He is survived by a son and two daughters, and to them the sympathy of his friends and colleagues will be extended.—J S H

Dr GEORGE DE JONCOURT PATTERSON of Lechlade, Gloucestershire, died on Sept 19 at the age of 91. He had been confined to bed for some months with gradually increasing weakness but his mental faculties, always acute, were quite undimmed up to the time when he peacefully lost consciousness. He was a B.A. of Dublin and graduated M.B., B.Ch. in 1881 proceeding M.D. in 1902. He made his own way in the profession and became a family doctor of the best type respected and liked in his practice at Heckmondwike in Yorkshire. He worked there for thirty-one years, and at Lechlade from 1915 until he retired, still full of energy, in 1932. Midwifery was always Dr Patterson's strong point. He was ideally suited for it with his calmness and patience, his natural aptitude, and his training at the Rotunda. He said he liked midwifery because he was so fond of seeing the smiling mother the next day. He saw many smiling faces in his fifty years of work and not only smiling mothers but all kinds of cheerful faces in his long and happy life. They were mirrors of his own face which was very seldom clouded with impatience.—H E B

Dr JOTINDRANATH GHOSH died at the Salford Royal Infirmary on Sept. 24, at the age of 61. Beyond the fact that he is said to have been a Bengali and to have been born at Coal Harbour Calcutta, on Oct 16, 1886, nothing is known of his early life. He died without a relative in the world. His medical school was Grant Medical College, Bombay, and he obtained the L.M.S. there in 1910. He appears to have come to Britain immediately afterwards for he took the D.P.H. in Dublin in 1912 and the FRCSI in 1913. During the first world war he was an A.M.O. at Portsmouth for three years, and in 1916 was appointed house-surgeon and later R.S.O. at Salford Royal Hospital. After a period he changed over from surgery and he served Salford Royal and Hope Hospitals as an anaesthetist efficiently, silently and kindly until a week or two before his death. In 1926 he was appointed visiting radiologist to Hope Hospital and combined these duties with his others. Most of us would say that his life had been spoilt by ill-health. It would not have been his own view. Many years ago while giving an anaesthetic his quiet voice inquired of the surgeon if the operation would take much longer. The surgeon thinking that the patient's condition was giving rise to anxiety, asked why. The reply was 'I shall be the next patient on this table. My gastric ulcer has just perforated. Within an hour it had been operated on. Unhappily, the succeeding years necessitated no fewer than six further major abdominal operations and it was the last one which led to his death. Yet though he suffered intense pain very frequently no murmur ever passed his lips, and it is doubtful if less intimate colleagues knew he was not

all Throughout all aspects of his life Joe was one of the most retiring and humble of individuals. His home, in which he lived alone was a treasure house of books, cut glass china, postage stamps and pianos. He admitted—he would never claim—that his collection of dictionaries, which formed part of some 6000 volumes, was superior to that in the Rylands Library. No one knows how many languages he spoke. He was an authority on Sanskrit and to him high authority appertained for assistance when in doubt. His command of the English language was superb, and though he never made his mark in his profession by any published works or in the outside world by any public action, to a very wide circle of friends he was invariably spoken of and to with love and deference.—W S C

### UNIVERSITY OF LONDON

John Vivian Dacie MB BS (Lond) has been appointed to the University Readership in Haematology tenable at the Postgraduate Medical School of London as from Oct 1, 1948

Sir Henry Dale, OM, GBE, FRCP, FRS, has been re-appointed a Crown Member of the Court for a further period of five years from Oct 1

J R Learmonth CBE, FRCS(Ed), regius professor of clinical surgery and professor of surgery in the University of Edinburgh, has been appointed Heath Clark Lecturer for 1949 and has been invited to deliver a course of lectures on 'The Contribution of Surgery to Preventive Medicine'

### UNIVERSITY OF LEEDS

The following candidates have been approved at the examinations indicated

MD—E Cope (with distinction) Dorothy D Jones J H Kahn S Lask H Lee S Madden R H Seville

FINAL MB ChB—Part III (Medicine Surgery Obstetrics and Gynaecology Therapeutics) H Black Ellen M Chippindale J W Daggett M Dales R England Kathleen Gillen Roxie Gossop Edwina E Green D C Hall R T Heytings E Menchovsky C H Morris Sarah L S Phillips Marjorie Pitman Elizabeth Price Jones P J Reynolds P D Roberts Etienne Sandford C J Sharp Barbara Welburn A B Wharton J C Woodrow D P Wright

The West Riding Panel Practitioners Prize has been awarded to J R Bowler

The *London Gazette* has announced the award of the Albert Medal to ARTHUR RICHARD CECIL BUTSON, MB, BChir, a member of the Falkland Islands Dependencies Survey, in recognition of his gallantry. The citation reads as follows: 'On the evening of July 26, 1947, an American member of the Ronne Antarctic Research Expedition fell into a crevasse some six miles from Base. Two teams were sent to the rescue but the hazards of crossing a heavily crevassed glacier were much increased by darkness and it was not until 4 o'clock on the morning of July 27 that the crevasse into which the American had fallen was located. Butson immediately volunteered to be lowered into the crevasse where he found the American tightly wedged 106 ft down and suffering from shock and exhaustion. For nearly an hour he had to chip the ice away in an extremely confined space in order to free the American who was brought to the surface and placed inside a tent. Butson then rendered the necessary medical aid and at dawn a return to Base was made carrying the American on one of the sledges.'

## Medical News

### Emergency Reserve Schemes

The Ministry of Labour and National Service has announced the setting up of Emergency Reserve Schemes, the object of which is to enrol volunteers with Service experience who would be urgently needed in the early stages of any emergency. For the time being, volunteers will not be accepted from a number of industries or services and from the following groups: (1) State registered nurse and midwives, (2) Student nurses pupil assistant nurses, and pupil midwives, (3) Medical, dental, veterinary, and pharmaceutical students. Among those persons who can be accepted only provisionally as volunteers are members of the medical profession, dentists and veterinary surgeons, enrolled assistant nurses and mental nursing assistants, opticians, pathological laboratory assistants, pharmacists, physiotherapists, and radiographers.

### Royal College of Obstetricians and Gynaecologists Dinner

The annual dinner of the Royal College of Obstetricians and Gynaecologists was held at the Dorchester on Friday, Oct 1. Replying to the Dowager Marchioness of Reading, who proposed the toast of the College, Sir William Gilliatt, the President, referred to the revolutionary changes brought about by the National Health Service Act. The College would be represented on the statutory advisory committee on midwifery and they would continue to press the Minister to maintain the highest level of efficiency in the midwifery services. The toast of the guests was proposed by Dr V B Green, Armytage. Dr Emil Novak, President of the American Gynecological Society, who earlier in the day had been elected an honorary fellow of the College, handed over to Sir William Gilliatt a gavel which had been made from a door knob in the house at Danville where Ephraim McDowell performed the first ovariotomy on Jane Todd Crawford in 1809. The gavel, which is a replica of that used by the American Gynecological Society, is inscribed 'Presented to Royal College of Obstetricians and Gynecologists by the American Gynecological Society, October 1, 1948'. Sir Henry Dale as President of the Royal Society of Medicine, also replied for the guests and so did Mrs Finletter and Professor Newell W Philpott. Professor Philpott paid tribute to the work done in Canada over the last few months by Sir William Fletcher Shaw, work which had led to the setting up of a regional council of the Royal College.

### King's College Hospital Medical School Dinner

At the annual dinner of King's College Hospital Medical School which was held at the Mayfair Hotel on Oct 2 with Mr John Everidge presiding, two different points of view were expressed about nationalized medicine. Dr Macdonald Critchley, proposing the toast of the Medical School mentioned excessive regimentation and the multiplicity of committees as being serious handicaps to clinical research. Professor Henry Cohen, replying to the toast of the guests proposed by Sir Cecil Wakeley, said he was convinced that it was essential for those in practice to devote some of their time to committee work in order to establish acceptable conditions. Mr H C Edwards, the Dean of the Medical School referred to the overcrowded syllabus of instruction. He looked forward to the day when it would be said about King's that they had stopped instructing students and had started to educate them. Dr Wilfred Attenborough proposed the health of the chairman, and in responding Mr Everidge mentioned some well known King's men of a past generation and expressed his confidence in the future of the medical school and hospital.

### Middlesex Hospital Dinner

The future of the Middlesex Hospital was referred to by Mr M H Whiting at the annual dinner held at the Savoy Hotel on Oct 1. He said that the hospital to which he first came in 1907, had wonderful buildings and well equipped laboratories. In the new era there must be enough money to keep them in perfect order. A ship and her crew were one and it was to be hoped that when the ship continued her voyage in strange and uncharted seas the crew would preserve and enhance the fine reputation of the hospital and medical school. Dr H E A Boldero emphasized the importance for teaching of the hospital's new association with the Woodside Hospital for Functional Nervous Disorders the Arthur Stanley Institute, and the Hospital for Women, in Soho. He also stressed the advantage of a medical school now having a charter. Dr R S C Couch, senior Broderip scholar was glad to see women students in the medical school and regretted that national service regulations limited the experience of young men in hospital appointments immediately after qualification.

### Doctors' Two Duties

Addressing Westminster Medical School at the inauguration of the academic session, Dr W J S Stallybrass, Vice-Chancellor of the Oxford University, said that one result of the Act was that the duty of public patients now owed two duties—one to the patient and one

*'everything  
seems to go wrong...'*

How often you hear it in your surgery! People today, harassed and run down, find themselves unable to contend with all the small irritations and minor mishaps of life

Livogen is invaluable in all cases of nervous depression, reduced vitality and general debility. It restores vitality rationally, by supplementing the normal resources of the body. It is a balanced composition of liquid extract of liver B.P., extract of yeast, vitamin B<sub>1</sub> and

nicotinic acid. Bottles of 4 and 16 fluid ounces are available as well as bottles of 80 fluid ounces for dispensing. Literature is available to medical men on request.

THE SPECIFIC AGENT  
AGAINST GRAM-NEGATIVE  
ORGANISMS

**PHENOXYETOL**  
NIPA

Phenoxytol is effective against Penicillin resistant organisms and compatible with Penicillin

Phenoxytol is not inactivated in the presence of serum

Phenoxytol is especially effective against gram-negative organisms including *Ps. pyocyanea*. It is used by local application in the treatment of infected wounds, abscesses, indolent ulcers associated with *Ps. pyocyanea*.

Phenoxytol is very effective in *pyocyanea* infections of burns or superficial wounds. It is especially useful in the preparation of surfaces for skin grafting associated with *Ps. pyocyanea*, and may also be used together with Penicillin in solutions and creams.

Phenoxytol should not be used for parenteral injection.

## Left Ventricular Failure...

In manifestations of left ventricular failure the action of Cardophylin may be of great value. This action is probably two fold, consisting of an increased blood supply to the failing myocardium as a result of coronary vasodilatation and a direct stimulating effect on respiration.

## Cardophylin

(THEOPHYLLINE ETHYLENEDIAMINE)

**VASODILATOR, RESPIRATORY

# ALLANTOIN SULPHANILAMIDE

## Bacteriostasis PLUS

Genatosan presents a unique range of Allantoin Sulphanilamide preparations for use by the surgeon and general practitioner

Allantoin brings about chemical debridement of necrotic tissue promotes tissue granulation and vascularisation, and exerts a synergistic effect with Sulphanilamide

The combination of Allantoin and Sulphanilamide is a very valuable one since not only is bacteriostasis achieved with Sulphanilamide but attention is also attracted to the healing process

### The series of

### 'GENATOSAN' ALLANTOIN-SULPHANILAMIDE

#### preparations include —

OINTMENT Allantoin 2% Sulphanilamide 5% in compound wool fat base

POWDER Allantoin 4% Sulphanilamide 96%

DUSTING POWDER Allantoin 2% Sulphanilamide 10%

CREAM Dermatological Cream No 2 (Allantoin 2%, Benzocaine 1%, Sulphanilamide 5%)

#### INDICATIONS —

Varicose ulcers and eczema slow healing wounds decubitus ulcers and other skin lesions

Information and literature available upon request

## Painless INTRAMUSCULAR INJECTIONS

e.g. of PENICILLIN, LIVER EXTRACTS,  
ARSENIC BENZOLS, BISMUTH, etc.

Many substances create some pain on intramuscular injection. Novutox injected at the same time will prevent this pain.

Most substances are compatible with Novutox, which is also non-destructive to penicillin during the time that the latter is undergoing absorption.

Mixtures with Novutox should be made  
immediately before use **ONLY**

## NOVUTOX

Self-Sterilising

Local Anaesthetic

Each c.c. of Novutox 2% contains 0.02 gm. ethocaine hcl, 0.00002 gm. epinephrine and 0.00002 gm. capryl hydrocupreinotoxin hcl. Other strengths of Novutox contain these elements (with or without epinephrine) in varying proportions.

to the State. That had a bearing on the old question whether a doctor should tell. He understood that at present registration forms were open to inspection by any member of a regional board, so that it might follow that an employer serving on the regional board could discover information detrimental to any employee. It was of vital importance that the communications made to a doctor should be known to be confidential. Turning to the problem of the expert witness, he asked whether, now that all doctors were paid by the State, it was right that some of them should always appear as witnesses for the prosecution and others for the defence. Would it not be more satisfactory if there were a panel of expert witnesses on subjects like insanity? But the Bench was suspicious of expert witnesses.

#### Nuffield Medical Fellowships

In the past the Nuffield Foundation has offered medical fellowships each year in four subjects—child health, industrial health, social medicine, and psychiatry. From 1949 the scheme will be widened to include all branches of medicine, though special consideration will still be given to those whose interests lie in the subjects listed. In general the Foundation will award these fellowships to people who wish to qualify for an academic career as teachers and research workers. Applications for awards in 1949 should be received not later than April 1, 1949, by the Secretary, Nuffield Foundation, 12 and 13, Mecklenburgh Square, London, W C 1.

#### Princess Tsahai Memorial Hospital Fund

An exhibition of British and Ethiopian children's drawings will be held at Seymour Hall, Seymour Place, London, W 1, on Nov. 8, 2 to 5 p.m., and Nov. 9, 11 a.m. to 5 p.m. The exhibition is promoted by the Princess Tsahai Memorial Hospital Council, and a bazaar on behalf of the hospital fund will be held in the same building. The Memorial Hospital Council will be pleased to receive gifts for the bazaar; they should be addressed to the Bazaar Secretary, 3, Charteris Road, Woodford Green, Essex. Donations to the hospital fund will be gratefully acknowledged by Lord Horder and Lord Amulree, c/o H. Reynolds & Co., 1, Bloomsbury Court, London, W C 1.

#### Higher Nurses' Salaries

The Council of the Royal College of Nursing resolved at a meeting held on Sept. 28 that the Functional Whitley Council for Nurses and Midwives be urged to take immediate steps to improve the salaries of trained nursing staff in the National Health Service. It suggests that salaries should be raised by just over £100. Moreover, the nurse's salary should be so calculated as to cover her responsibilities fully, such as the teaching of practical nursing, and compensate her for such features of the nurse's life as spread over duties and week-end work.

#### Poor relief Statistics End

A Government publication which has appeared annually almost without a break for 100 years is now issued for the last time. It is the return which since 1919 has been issued by the Ministry of Health showing the number of persons in receipt of poor-law relief. It has been ended because the poor law system has been swept away by the National Assistance Act. The final return (H.M.S.O., 9d) records that the number of men, women, and children in receipt of poor relief in England and Wales at Jan. 1, 1948, was 469,556. This was 7,372 fewer than at the same date a year earlier. The number of children was 137,442. Among the categories of persons were 1,721 casuals, compared with 1,545 a year before. There were also 2,333 orphans (both parents dead), 1,040 of whom were receiving institutional relief. Only 1,585 were receiving relief because of unemployment. When the first return in this series was compiled the number of people receiving poor relief in England and Wales in July 1848 was 893,743. During the following century the highest total of persons in receipt of poor relief was returned on Jan. 1, 1935, when it reached 1,472,891. Of these, 452,075 persons were receiving relief because of unemployment. On Jan. 1, 1922, 744,797 persons received relief because of unemployment, the highest total for this cause recorded.

#### Christmas Cards

The Grenfell Association has once again produced a delightful series of Christmas cards depicting the arctic scenery of Labrador and Northern Newfoundland, where it carries out its invaluable medical work. Profits from the sale of these cards help the work to continue among the fishermen and fur traders. Funds are desperately needed for fish and fur have been scarce for two years with the result that food and clothing are short and the dogs on which transport depends in winter, have died. Tuberculosis is reported to be dangerously increasing and some of the original wooden hospitals which have withstood the arctic storms for over 40 years must be rebuilt. Cards are available in black and white or in colour at prices from 9d to 1s. Packets of six postcards may be bought for 2s., and stamps for philatelists are sold. There is also an illustrated leaflet price 1d. Orders for Christmas cards should be addressed

to the Secretary, Grenfell Association, 6, Victoria Street, London, S W 1, or to Miss Betty Fyfe, Westland, Kilmalcolm, Renfrewshire. The stamps may be obtained from Mrs. D. M. MacKay, 88, Exeter House, Putney Heath, London, S W 15.

### COMING EVENTS

#### Royal Society of Medicine

Dr. Philip S. Hench, of the Mayo Clinic, will give the Samuel Hyde Lecture before the Section of Physical Medicine of the Royal Society of Medicine, 1, Wimpole Street, London, W, on Wednesday, Oct. 13, at 4.30 p.m. The title of the lecture is 'A critical evaluation of current remedies for rheumatoid arthritis.' The Officers of the Section extend a cordial invitation to those who are not Fellows of the Society to attend. Admission to non-Fellows will be by ticket only, and application should be made to Dr. Doris Baker, Honorary Secretary of the Section, at 1, Wimpole Street.

#### Industrial Health Lecture

An address on 'An Industrial Health Service' will be given by Dr. E. H. Capel, chief medical officer to the National Coal Board, to the North-west Middlesex Branch of the Socialist Medical Association on Oct. 14 at the Town Hall, Wembley. It will be preceded by a C.O.I. film, 'They Live Again,' at 7.30 p.m.

#### University of Leeds

The inaugural lecture of the Faculty of Medicine of the University of Leeds will be given in the Riley-Smith Hall of the University Union on Tuesday, Oct. 12, at 3 p.m., by Professor W. E. Le Gros Clark, F.R.S. His subject is 'Intellectual Adventure.' Members of the medical profession are invited to be present.

#### Facilitation of Visual Tasks

The 23rd Ettles Memorial Lecture will be delivered under the auspices of the Association of Optical Practitioners by Mr. H. C. Weston at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Wednesday, Oct. 13, at 7.45 p.m. His subject is 'The Facilitation of Visual Tasks, with Special Reference to Near Visual Problems.' Admission to the lecture is free, and all those interested are invited to attend.

#### Society of Medical Officers of Health

At the first ordinary meeting of the Society of Medical Officers of Health for the session 1948-9, on Thursday, Oct. 14 at 5.40 p.m., R. H. Parry, M.D., F.R.C.P., D.P.H., Medical Officer of Health for the City of Bristol and Professor of Preventive Medicine in the University of Bristol, will be installed as president of the society and will deliver his presidential address.

#### Society of Chemical Industry

A joint meeting of the Nutrition and Microbiological Panels of the Food Group of the Society of Chemical Industry will be held at Gas Industry House (No. 3 Room), 1, Grosvenor Place, London, S.W., on Wednesday, Oct. 13, at 6.15 p.m., when Dr. E. F. Gale will read a paper entitled 'The Role of Vitamins and Metals as Co-enzymes in Bacterial Metabolism.'

#### Chelsea Clinical Society

Chelsea Clinical Society will hold the opening meeting of the 1948-9 session at the South Kensington Hotel, 47, Queens Gate Terrace, London, S.W.7, on Oct. 12 at 7 for 7.30 p.m. Discussion on 'Empiricism in Medicine' to be opened by Mr. Geoffrey Evans.

#### National Safety Congress

The public safety sessions of the 1948 National Safety Congress, organized by the Royal Society for the Prevention of Accidents (Terminal House, 52, Grosvenor Gardens, London S.W.1), will be held at the Central Hall, Westminster, London S.W., from Tuesday to Friday, Oct. 12 to 15. At the child safety session on Oct. 13 Dr. Charles Hill, Secretary of the British Medical Association, will speak on 'The Road Safety of the Young Child' and at the home safety session on Oct. 14 'Home Dangers to the Under Fives' will be discussed by Dr. J. L. Burn. The full programme may be obtained from the secretary of the society at the above address.

#### American Group Therapy Association

The sixth Annual Conference of the American Group Therapy Association will be held on Jan. 21 and 22, 1949, at the Engham Auditorium, Lenox Hill Hospital, New York. One session of the conference will be on analysis of the nature of leadership in ordinary groups and therapy groups. Dr. S. H. Foulkes (England) will deliver one of the main papers in this symposium. The topic of another session is 'Contemporary Research in Group Psychotherapy.' The Association's address is 228, East 19th Street, New York 3, New York.

## SOCIETIES AND LECTURES

## Monday

MEDICAL SOCIETY OF LONDON 11, Chandos Street, Cavendish Square

## EPIDEMIOLOGICAL NOTES

## June Quarter, 1948

The latest quarterly return, issued on Oct 7, contains some further vital statistics for the years 1946 and 1947. The general mortality ratio (the ratio of mortality from all causes to that of the previous year) for 1947 is given as 1 028 compared with 0 987 in 1946. The infant mortality rate for the year 1947 was 41 per 1,000 related live births against 43 in 1946. This is the lowest rate of deaths of children under one year of age ever recorded for a complete year in this country, although the provisional rate for the June quarter of 1948 was 31 which is the lowest for any quarter recorded in this country.

The number of civilian deaths from diphtheria continued to fall in 1947, there being only 242 compared with 455 in 1946 and 1,348 in 1943. This was the lowest number ever recorded in England and Wales. Civilian deaths from influenza numbered 3,303 in 1947, compared with 2,669 and 5,272 in the two preceding years and 12,576 in 1943. Deaths from influenza in the second quarter of 1948 (provisional total excluding non-civilians) numbered only 204.

The prevalence of acute poliomyelitis and polio-encephalitis during 1947 resulted in 688 civilian deaths (407 males and 281 females) compared with 116 and 126 in 1946 and 1945 respectively. Deaths from these causes in the second quarter of 1948 (provisional total excluding non-civilians) numbered 27 compared with 40, 429, 196, and 82 in the four preceding quarters.

There were 31 469 civilian deaths from bronchitis and 22,659 from pneumonia during 1947, which was more than for any year since 1943, when the corresponding figures were 31 386 and 24 638 respectively.

## Discussion of Table

In *England and Wales* there were decreases in the notifications of whooping cough 242, dysentery 34, and paratyphoid 15; the only increase was in the incidence of scarlet fever 92.

The rise in the notifications of scarlet fever was due to small increases throughout the northern section of the country, in the southern section no change occurred. A small fall in the notifications of measles was recorded in most areas, the only exceptions of note were rises in Yorkshire West Riding 97 and Cumberland 99. The rise in the latter country was due to outbreaks in Maryport UD 83 and Cockermouth RD 25.

The largest falls in the incidence of whooping cough were London 63, Middlesex 58, and Lancashire 59; the largest rise was Yorkshire West Riding 67. A decrease of 8 in the notifications of diphtheria in Lancashire was the chief feature of the returns of this disease.

A further 16 cases of typhoid fever were notified from the outbreak in Shropshire, Oswestry RD. An outbreak of dysentery affecting 11 persons was notified from Somerset, Taunton MB, and this was the largest centre of infection during the week.

There was no change in the number of notifications of acute poliomyelitis, the largest returns were Lancashire 7, London 6, Gloucestershire 5, Glamorganshire 5, Norfolk 5, Warwickshire 5, Essex 5, Buckinghamshire 4, Cheshire 4, and Middlesex 4.

In *Scotland* decreases occurred in the notifications of whooping-cough 42, diphtheria 26, and dysentery 14, and a rise of 23 was recorded for scarlet fever. The increase in scarlet fever was due to a rise in the western area, all counties in this area had an increased incidence except Lanarkshire where the notifications decreased by 16.

In *Eire* increases were recorded for scarlet fever 36 and diarrhoea and enteritis 12, while decreases were reported for measles 17 and whooping cough 9. An increase in the incidence of scarlet fever occurred in most areas, and in Dublin CB the notifications were 15 more than in the preceding week. The incidence of diarrhoea and enteritis in Dublin CB remained unchanged.

In *Northern Ireland* an increase of 20 in the notifications of scarlet fever was the chief feature of the returns. There was a small rise in the notifications of scarlet fever throughout the country.

## Week Ending September 25

The notifications of infectious diseases in *England and Wales* during the week included: scarlet fever 1 068, whooping-cough 2 259, diphtheria 125, measles 2 703, acute pneumonia 277, cerebro-spinal fever 26, acute poliomyelitis 70, dysentery 68, paratyphoid 15, and typhoid 29.

The Ministry of Health has announced that persons who are incapable of work by reason of mental disablement must be registered for National Insurance and pay contributions as non-employed persons. The only exceptions are children under the age of 15, men over the age of 65, and women over the age of 60.

## Any Questions?

## Treatment of "Tennis Elbow"

**Q**—*What is the latest treatment for tennis elbow? I have been plagued with this condition for about six months and it is steadily getting worse. In its earliest stages I thought I had mildly bruised the external condyle, now I can scarcely lift a small book. X rays reveal no abnormality in or round the joint. No focus of infection can be found. Manipulations by an orthopaedic surgeon produced no results. The same applies to ultra-short-wave therapy and massage, pressure bandaging and simply leaving it alone.*

**A**—Many forms of treatment are in common use for the relief of 'tennis elbow'. No single one of them except operation, can be relied upon to produce rapid relief in a given case. It is usual to start with the simplest measures such as short-wave diathermy, deep massage, and faradism to the extensor muscles of the forearm. If these are unsuccessful the injection of a solution of local analgesic into the exact site of the tenderness may occasionally give dramatic results. It is worth while repeating the injection if the first is incompletely successful. If this also fails the effect of immobilization in plaster should be tried. The plaster should extend from the upper arm to the metacarpal heads and should hold the elbow at 90 degrees. The immobilization should be maintained for six to eight weeks. It is successful in a fair proportion of cases. Manipulation under anaesthesia (local or general) is also worth a trial in obstinate cases.

As a last resort operative treatment may have to be considered, but as 'tennis elbow' will almost invariably resolve spontaneously if given sufficient time (often twelve months or more) operation should not be advised unless the condition is severe enough to cause significant incapacity. The operation consists in raising the humeral origin of the forearm extensor muscles from the bone and displacing it downwards. This is the most certain way of relieving the symptoms within a reasonable time and in some cases it will be advised in preference to the more time-consuming conservative methods simply on economic grounds.

## Squatting in Congenital Heart Disease

**Q**—*What are the mechanics of squatting? This position is adopted not only by young patients with congenital heart disease but also by patients with congestive heart failure from rheumatic carditis and from bronchial asthma. These patients may be seen in hospital in bed with knees up and body and head forward, the elbow being on the bed-table, the resulting position being very nearly the same as the squat.*

**A**—No explanation has been put forward to account for the squatting position in congenital heart disease. It is possible that in the squatting position the pressure of the thighs on the abdomen and its contents increases the venous return to the heart and so increases the cardiac output. This temporarily improves the oxygen supply to the body tissues, the blood oxygen saturation remaining the same. In the case of asthma and congestive failure from rheumatic heart disease, the essential point is the elbows being on the bed-table. This fixes the head of the humerus near which the pectoralis muscles and latissimus dorsi are inserted. This then becomes the origin of these muscles, which are used as accessory muscles of respiration in an attempt further to expand the thoracic cavity. The knees are drawn up automatically in sitting forward on the bed-table.

## Stable Solution of Calcium Gluconate

**Q**—*What is the most reliable method of preparing stable solutions of calcium gluconate (10% and 20%) for injection purposes? What are the stabilizers generally used and in what concentration? Of late calcium laevulinate is becoming popular—how is it manufactured?*

**A**—The *British Pharmacopoeia* solution of calcium gluconate for injection is a supersaturated solution of 10% pure calcium gluconate prepared by dissolving it in the B.P. water for injection with the aid of heat and clarifying the hot solution by passing through a suitable filter. While still hot the solution is distributed into carefully washed ampoules which are then

## AN INQUIRY INTO THE EFFECT OF H 11 IN THE TREATMENT OF MALIGNANT DISEASE

REPORT OF A COMMITTEE\* APPOINTED BY THE MEDICAL RESEARCH COUNCIL

According to Thompson *et al* (1941) the substance H 11, which is an extract prepared from a concentrate of normal human urine, has an inhibitory action on malignant tissues in the human being, and may in certain cases lead to recovery from cancer. Their claim is founded on the results of animal experiments and of the treatment of human beings.

Although no claim for a cancer cure has been specifically made, it is clear from the published reports that the clinical improvement mentioned is associated with the "arrest" of the growth said to be produced by the treatment with H 11, and that disappearance of symptoms, in some cases amounting to "cure," is said to follow the "regression" of the growth. The implication clearly has been that the substance has clinical value, and as a result interest has been aroused.

Advocates of the alleged remedy have said that responsible bodies, in particular the Medical Research Council, by withholding support and refusing to recognize work which marks an advance in the treatment of cancer. It was therefore decided that the Medical Research Council should appoint a special committee, and this was done in November, 1944. The primary task of the committee was to collect the available evidence on which the claims for H 11 were based and to assess its value. At this point the committee would like to acknowledge that all the information received by the Hosa Research Laboratories was placed at its disposal.

The committee approached this inquiry in two ways—namely, (1) a study of the clinical case records supplied by the Hosa Laboratories in order to find out the results of administering H 11 to human patients suffering from cancer, (2) an experimental investigation into the effect of H 11 upon malignant tumours in mice. In addition to these two approaches all the available literature on the subject has been carefully examined.

### Study of the Clinical Case Records

An attempt was made to assess the results of administering H 11 to human patients. It is obvious that the laboratory method of control is not applicable to man. In the case of cancer, therefore, the only substitute for strict control has been the comparison of records of patients not treated in some other way, with the records of patients treated in the particular way under study. At the request of the committee's study the Hosa Laboratories had made available clinical case records of over 3,000 patients who had

been treated by their doctors with injections of H 11 supplied to them by the Hosa Laboratories. The committee appointed Dr Dora Colebrook to make a detailed extract of these records. The Hosa Laboratories put all the records at her disposal, and she, with the co-operation of Dr Ollerenshaw, of the staff of the Hosa Laboratories, transcribed the findings in Hosa case records on to special forms which had been drawn up for the purpose. Dr Colebrook extracted the information in this way from 1,000 case records. Before continuing with this work the committee concluded that it must first determine whether the records available in the Hosa Laboratories were such as would ultimately allow any statistical analysis of value to be carried out and thus enable a conclusion to be reached.

For this purpose a random sample of 100 cases was drawn from the 1,000 case sheets extracted by Dr Colebrook. To these were added, again at random, 39 further records to give a wider picture of those cases in which the Hosa Laboratories considered that "arrest" or "regression" of the malignant growth had taken place. The complete details of these 139 records have been closely studied by the committee so that it might, from such representative groups, (1) examine the kind of evidence on which the Hosa claims rested, (2) consider whether the data could be used in a scientific assessment of the results of the treatment, and (3) decide whether any further analysis of the available 1,000 case records was warranted and whether extraction of the remaining 2,000 to 3,000 records was desirable. In selecting this sample of the records for detailed study the committee had the advice of Professor Greenwood and Professor Bradford Hill.

The committee concluded that the assumptions made by Hosa with regard to the behaviour of malignant tumours are fallacious and that the recorded data on which their conclusions are founded cannot be used as the basis of a scientific judgment on the effect of the treatment.

One of the contentions of the Hosa staff is that the decrease in size (or volume) of a malignant tumour is necessarily a favourable prognostic sign, and that a patient under treatment showing signs of diminution in size of the tumour is thereby giving evidence of regression of the disease. The committee is unable to accept this point of view. The reduction might be due to necrosis of cells without replacement by new formation, or to diminution of inflammatory reaction. Clinicians are quite familiar with such changes. A further point is that once metastases have formed subsequent changes at the primary site may have little or no bearing on prognosis.

In a review by E. Cronin Lowe (1944) of patients treated with H 11 there is a section on the subjective signs and symptoms. Pain is mentioned as a prominent symptom in 150 cases, and in 98 reduction of pain is reported. It is suggested that this reduction of pain is evidence of the

\*Members of the committee were Professor G. E. Gask, the Right Hon. Lord Balfour of Burleigh, Sir Ernest Jones, Professor M. Greenwood, Professor A. Bradford Hill, J. R. Leitch, Professor M. J. Stewart, Professor L. J. and Dr. Mary Gilmour (Secretary).

value of the treatment. The committee is unable to accept this claim. No control is available. In all diseases pain is a variable symptom.

The Ministry of Health has in the past issued a series of reports by Dr Janet Lane-Claydon and others on cancer and the results in terms of survivorship of various forms of treatment. It was hoped that a comparison might be made of these results, as well as of the survivorship of untreated patients, with those of the Hosa records of patients treated with H 11, but in fact it was not found possible to do so. The ultimate test of the value of any form of treatment in cancer is survivorship. If it can be proved that patients suffering from cancer treated in a certain way live longer than patients untreated or treated by other methods, then it may be claimed that some success has been achieved. The Hosa records do not enable the committee to determine the average length of life of patients treated even from the time of the first treatment with H 11, still less from the first date, or alleged date, of the onset of the disease. It is impossible to obtain from these records anything to compare statistically with such analyses as those published by the Ministry of Health.

After making a prolonged study of the analysis of the Hosa case sheets referred to above the committee has arrived at the conclusion that details of the onset of the disease are often lacking as well as records of the total duration of survivorship and duration of survival after the beginning of treatment with H 11. The conclusion it has come to is that it is unable to infer from the Hosa records that the administration of H 11 to those patients did in fact have any effect on the growth of the cancer or prolong the life of the patients. To attempt to follow up the subsequent life histories of the patients by inquiry of general practitioners or through the Registrars-General would involve an amount of time and labour incommensurate with the results likely to be achieved. Enough information is now available on which to form an opinion, and further work on the records is not advised. In short, the records are not such as to supply any valid evidence which can be statistically analysed. To illustrate the clinical histories from which the Hosa Laboratories deduce that "arrest" or "regression" has taken place the committee gives in Appendix 1 the summaries of 25 cases selected at random.

#### The Effect of H 11 on Animals Suffering from Cancer

H 11 was reported by Thompson *et al* (1941) to inhibit growth of the Twort carcinoma, a tumour which can be grafted in mice and which in favourable circumstances can be carried through many generations. It is, however, well known to experimental pathologists that this particular tumour is especially liable to regress and even to disappear without any treatment of the tumour-bearing animals.

In 1943 Dr Gye, Director of the Imperial Cancer Research Fund and Professor of Experimental Pathology in the Royal College of Surgeons, was invited by the President of the Royal College of Surgeons to test the value of H 11 in animals. Dr Gye, being fully aware of the liability of the Twort carcinoma to spontaneous regression, and regarding this particular tumour for that reason as unsuitable, employed in his experiments not the Twort tumour but the mouse mammary carcinoma known as M 63 and other tumours which he regarded as more stable and therefore more likely to give a true answer. In July, 1943, Dr Gye published his results. *His conclusions were that H 11 had no growth-inhibiting effects on the tumours used in his experiments.*

Mr Thompson (1943) objected that this research was irrelevant as the claim of the Hosa Laboratories in the experimental field was made with respect to the Twort

carcinoma only. He objected, further, that neither the strain of mouse used nor the manner of administration nor the dosage chosen was appropriate. It may be remarked here that no evidence has ever been produced that the Twort tumour has any closer biological analogy with cancer occurring in human beings than have the mouse tumours used in Dr Gye's experiments.

After careful consideration the committee decided that a satisfactory conclusion could not be reached until the objections raised by Mr Thompson had been fully investigated. The committee accordingly sought for an entirely independent expert who would conduct a further series of experiments using the Twort tumour under conditions laid down by Mr Thompson. The choice of the committee fell on Dr Georgiana M. Bonser, Brotherton Fellow in Cancer Research in the University of Leeds, who kindly consented to undertake this long and laborious series of experiments.

Dr Bonser has conducted a series of animal experiments extending over many months. She has used the Twort tumour in five of the experiments. In addition she has performed two parallel experiments using (a) mice grafted with a spindle-cell sarcoma, (b) mice bearing spontaneous mammary cancer. A full account of these investigations has been prepared by Dr Bonser, and is included in Appendix 2. *The conclusion of her inquiry, confirming that reached by Dr Gye, is that there is no evidence that H 11 had any growth-inhibitory effect in any of the experiments carried out.*

The committee, having considered Dr Bonser's report, entirely agrees with the above conclusion. In the opinion of the committee this memorandum also fully confirms Dr Gye's conclusion that the Twort tumour is not a suitable tumour on which to test therapeutic substances, in consequence of its great liability to spontaneous regression.

The committee, after taking further expert advice, is of the opinion that no useful purpose will be served by undertaking experiments designed to test the theory of optimum volume and concentration in dosage so heavily stressed by the Hosa staff. In its opinion the theory as applied to H 11 is untenable in the light of existing knowledge.

Before writing their final report the committee invited Mr Thompson and Dr Ollerenshaw to meet it and to make any comments they wished on the findings of the committee.

#### The Committee's Conclusions

The conclusions at which the committee has arrived after careful consideration are: (1) It has not been possible to deduce from an analysis of the Hosa records that H 11 has any effect either on the rate of growth of cancer in man or on the clinical course of the disease. (2) So far as the experiments in mice carried out under its direction are concerned no inhibitory action by H 11 has been demonstrated.

#### APPENDIX 1

A random sample of the case histories extracted from the Hosa records and from the associated reports sent to the Hosa Laboratories by the medical attendants of the patients.

For the guidance of the reader the following are the criteria laid down by the Hosa Laboratories for their assessment of the results of treatment with H 11. The committee is indebted to Dr Ollerenshaw of the Hosa Laboratories staff, for this

atement of their methods of classification (and also for having checked the accuracy of each of the sample case records which were extracted for the committee's particular study)

"1 The method of classification of results in use is based solely on the result of treatment as shown by the size of the neoplasms. It is not based in any way on the subjective response. Thus a patient showing an objective advance of disease but with marked relief of pain and other evidence of subjective response would be classified as failure (A).

2 It is assumed that a therapeutic procedure is 'of value' if it produces subjective improvement, objective improvement, or both. The lettered classification in use, indicating objective results only, does not therefore cover value shown by subjective response.

3 The classification used is as follows

A No indication of any objective effect on the disease

B Evidence of arrest or partial inhibition of growth for a period of two months or longer where the tumour/s had been actively increasing in size prior to treatment. If treatment has only been in progress for two months or slightly more arrest or partial inhibition is claimed if the tumour/s, previously growing, have ceased to grow.

C Clinical (or other adequate) evidence of regression of tumours as indicated by an observable decrease in size. In the case of visible or palpable tumours, regression can more easily be observed; in the case of internal or impalpable tumours, evidence of decrease in size is obtained from radiological or other special methods of examination."

In the body of the committee's report reference is made to a sample of 139 cases which, in the light of these definitions, the committee studied in detail. These records were at the same time submitted to the Hosa Laboratories, and their accuracy was, as stated above, checked by Dr Ollerenshaw. Arising from this check a few changes in the classifications were accepted by the committee—namely

(a) A patient classified as Group C (regression) was withdrawn from the series, since treatment with H 11 had been irregular and the series studied by the committee was defined as patients who had received at least two months' prescribed treatment.

(b) In eight cases the Hosa classification of the results of treatment had been changed with the passage of time—e.g., from arrest to regression. The committee had studied the situation at both points of time but the classification at the latest available point of time in the patient's history was finally adopted as that most relevant.

(c) One patient had two primary tumours—one showing "no objective improvement" (Group A) and the other classified as arrest (Group B). This case was included in both Group A and Group B.

With these slight adjustments the committee had for its final detailed study 139 case histories, relating to 138 patients, of which 47 had been allocated at the latest point of time to the Hosa Group B ('arrest') and 30 to its Group C ('regression'). The remainder at that point of time either showed "no objective improvement" (Group A) or had remained unclassified on account of insufficient evidence, etc.

Having examined the protocols of these cases the committee has stated in its report that it is entirely unable to accept the evidence upon which the arrest or regression of a tumour is based. To illustrate to others the nature of these cases and the available evidence the committee has taken at random every third case of the 47 'arrests' (15 cases) and of the 30 'regressions' (10 cases) and gives these 25 histories in detail below. These cases form a small but sufficiently illustrative sample of those in which the Hosa Laboratories conclude, in accordance with their criteria set out above, that there was evidence of either an arrest or a partial inhibition of a growth which had previously been actively increasing in size or of its regression as shown by an observable decrease in its size.

For convenience the 25 case histories are arranged in the following order

I Fifteen cases classified by the Hosa Laboratories as showing 'arrest' of the growth (Group B). (a) 12 dead when the committee's extract of the records was completed, (b) 3 known to have been alive on the date specified when they were last heard of by the Hosa Laboratories.

II Ten cases classified by the Hosa Laboratories as showing 'regression' of the growth (Group C). (a) 6 dead when the committee's extract of the records was completed, (b) 4 known to have been alive on the date specified when they were last heard of by the Hosa Laboratories.

In each case history the sex and age of the patient are given first, followed by the primary site and any available information on the growth—its size, etc. The summarized reports of subsequent progress from the patient's medical attendant include all the available evidence on objective changes, but they do not necessarily provide a comprehensive history of the case, as details may not in all instances have been sent in by the medical attendant. They also do not include reports on merely subjective changes—e.g., on general condition or pain—unless it appeared to the committee, in a few cases, that these reports had some bearing upon the Hosa Laboratories classification of the results of treatment with H 11. For the duration of treatment with H 11 the date of the first issue is given and one of the following alternatives: (a) the date of the last issue of the customary four-weeks supply; (b) the date of death if it occurred within four weeks after the last issue; (c) a specified date on which treatment was reported to have ceased.

### Group B

*Fifteen cases classified by the Hosa Laboratories as showing "arrest or partial inhibition of growth for a period of two months or longer where the tumour(s) had been actively increasing in size prior to treatment"*

1 M, 62, small intestine, secondaries, liver and glands, diagnosis colunar celled carcinoma, too advanced for operation, result of biopsy uncertain but probably positive, date not given, laparotomy, 1941, previous duration of disease and size of tumours not stated. Previous treatment none mentioned. H 11 first issue 24/11/41, last issue 16/4/43. Progress reports Dec, 1942, developing obstruction, Jan, 1943, lateral anastomosis, at operation primary reported to be larger and secondaries of the same size as at the laparotomy in 1941 (no evidence that the same observer was present at the two operations). Death, May, 1943.

2 M, 55, prostate, secondaries in pelvis, femur, and tibia, no report of a biopsy, diagnosis adenocarcinoma, advanced, previous duration of disease and size of tumours not stated. Previous treatment none mentioned. H 11 first issue 27/4/43, last issue 23/11/43 (with 3 months' interval from Aug to Nov, 1943 for a course of stilboestrol). Progress reports primary, Aug, 1943 (before stilboestrol) *in statu quo*, no report on secondaries, final report, "Did very well on stilboestrol". Death from uraemia and oedema, Jan, 1944.

3 F, 49, ovary, invading abdomen, diagnosis carcinoma, inoperable (date of laparotomy not given), microscopical section (date not given) "did not indicate a high degree of malignancy", previous duration of disease not stated. Previous treatment none mentioned. H 11 first issue 9/1/43, treatment ceased 1/7/44. Progress reports April, July, Sept, Dec, 1943, and July, 1944, *in statu quo* (Sept, 1943, "enormous"), final report, "Prolonged life". Death, Oct, 1944.

4 M, 62, pelvic colon (growth palpable), secondaries generalized in abdomen, diagnosis carcinoma, advanced, no report of a biopsy, but laparotomy, 1940, previous duration of disease and size of tumours not stated. Previous treatment colostomy, May, 1940. H 11 first issue 14/5/41, death 22/12/41. Progress reports Aug, 1941, ? slight decrease, Dec, 1941, marked increase with obstruction, laparotomy showed disseminated malignant peritonitis, final report, "No good effect". Death, Dec, 1941.

5 F, 59, rectum (tumour in wall 1 in by 2 in (2.5 by 5 cm), involving uterus and colon, secondaries in omentum, diagnosis adenocarcinoma, advanced, inoperable (no date), no report of a biopsy, but laparotomy, 1943, previous duration of disease not stated. Previous treatment colostomy just before start of H 11 treatment. H 11 first issue 9/12/43, death 23/5/44. Progress reports Feb, 1944, toxic, April, 1944, primary larger and softer, bacilluria, final report, dissemination of carcinoma. Death, May, 1944.

6 F, 62, ovaries, secondaries, omentum and peritoneum, diagnosis, confirmed by biopsy, 1944, adenocarcinoma, advanced, progress a few months, previous duration of disease and size of tumours not stated. Previous treatment, March, 1944, double oophorectomy, secondaries inoperable. H 11 first issue 3/4/44, last issue 25/7/44. Progress reports June, 1944, still palpable, Sept, 1944, much larger. Death from intestinal obstruction, Oct, 1944.

7 M, 61, pelvic colon, secondaries in peritoneum and liver, diagnosis carcinoma, advanced, no report of a biopsy, but laparotomy Oct, 1943, previous duration of disease and size of tumours not stated. Previous treatment colostomy, Oct, 1943. H 11 first issue 20/4/44, last issue 25/7/44. Progress reports Sept, 1944, liver enlarged, no report on primary. Death, Sept, 1944.

8 F, 60 breast, secondary, skull (2 small nodules), spine (3 collapsed vertebrae) diagnosis scirrhous carcinoma, advanced, confirmed by biopsy Dec, 1941, and secondaries by radiographs, previous duration of disease about 3 years Previous treatment radical amputation, Dec, 1941, no recurrence, radium, 1943, deep x rays, 1943 and 1944, 2 courses, "of no avail" H 11 first issue 15/5/44, death 28/8/44 Progress reports July, 1944, nodule in skull *in statu quo*, radiologist's report, "Vertebrae partly collapsed but better consolidated than before The condition is evidently due to metastases, but the improved consolidation suggests some bone regeneration" Death from rapid carcinomatosis, Aug, 1944

9 F, 72, breast, secondaries in glands, diagnosis carcinoma, advanced, no report of a biopsy previous duration of disease and size of tumours not stated Previous treatment radical amputation, 1938, deep x rays (4 applications), Feb, 1944 H 11 first issue 28/8/44, treatment ceased 12/5/45 Progress reports Oct, 1944, primary *in statu quo* secondaries larger, March, 1945, secondaries much larger, final report, "Hopeless to start with" Death, Oct, 1945

10 F, 49 cervix, secondary in left iliac fossa, diagnosis columnar celled carcinoma, confirmed by biopsy, Oct, 1943, advanced, prognosis 6 months, previous duration of disease not stated secondary reported as small Previous treatment pan-hysterectomy, Oct, 1943, no recurrence H 11 first issue 30/10/44 last issue 2/12/44 (ceased treatment Jan, 1945) Progress reports Dec, 1944, secondary *in statu quo*, Jan, 1945, "very much better" Final report general abdominal carcinomatosis, "H 11 seems to have prolonged life" Death, Jan, 1946

11 F, 34, breast, secondaries in bones, diagnosis carcinoma, confirmed by biopsy, 1941, advanced, 'hopeless', previous duration of disease and size of tumours not stated Previous treatment "amputation" May, 1941, no recurrence, deep x rays, Oct, 1944, stilboestrol, date not given H 11 first issue 12/1/45, treatment ceased 7/7/45 Progress reports May, 1945, secondaries new and enlarging, final report, "Objective improvement at first" Death, Oct, 1945

12 F, 64, breast, subcutaneous and pleural secondaries, diagnosis carcinoma, ? confirmed by biopsy, 1939, advanced, prognosis 12 months, previous duration of disease and size of tumours not stated Previous treatment radical amputation, Oct, 1939, no recurrence H 11 first issue 3/7/45, treatment ceased 23/9/45 Progress reports Sept, 1945, pleural effusion less, nodules *in statu quo*, Oct, 1945, nodules *in statu quo*, final report, "Slowed down rate of growth", arrest during treatment Death following haematemesis, Oct, 1945

13 F, 50, Fallopian tubes, secondary in vagina, diagnosis adenocarcinoma, no report of biopsy previous duration of disease and size of tumour not stated Previous treatment Dec, 1942, pan-hysterectomy H 11 first issue 25/5/43, last issue 19/8/43 Progress reports July 1943, vaginal haemorrhage, appeared to be moribund Aug, 1943, general condition much improved, haemorrhage ceased final report, Jan, 1944, "Has gone downhill since ceasing H 11, which kept the growth in abeyance" Last heard of Jan, 1944

14 M, age not given, pelvic colon, no secondaries, diagnosis carcinoma, advanced, prognosis ? 12 months, no biopsy, but laparotomy (date not given), previous duration of disease and size of tumour not stated Previous treatment colostomy (date not given) H 11 first issue 12/4/44 treatment ceased 12/8/44 Progress reports June, 1944, primary, *in statu quo*, Sept, 1944, liver enlarged, final report "No effect" Last heard of, Sept, 1944, moribund

15 M, 61, rectum (involving three quarters of circumference of gut), fixed, no secondaries, diagnosis carcinoma, prognosis 1 to 1½ years, no report of a biopsy, previous duration of the disease not stated Previous treatment colostomy, March, 1944 H 11 first issue 10/5/44, treatment ceased 22/12/44 Progress report, Sept, 1944, primary *in statu quo* Last heard of, Dec, 1944

### Group C

Ten cases classified by the Hosa Laboratories as showing clinical (or other adequate) evidence of regression of tumours as indicated by an observable decrease in size

16 M 42, rectum no secondaries mentioned, diagnosis carcinoma, confirmed by biopsy (date not given), advanced, prognosis 6 months, history of 18 months in bed and of rectal haemorrhage, size of tumour not stated Previous treatment none, inoperable (date not given) H 11 first issue March, 1942, death 23/3/43 Progress reports May, 1942, rectal haemorrhage had ceased, general condition markedly improved, Sept, 1942 walking and working, March, 1943, two tests for occult blood in faeces negative final report, "The agent appeared to be causing retrogression of the cancer" Death from uraemia, chronic nephrosclerosis, and bedsores, March 1943

17 M, 55, caccum, secondaries in mesenteric glands, diagnosis carcinoma, confirmed by biopsy, ? Dec, 1941, advanced, previous duration of disease and size of tumours not stated Previous treatment none H 11 first issue 2/1/42, death 11/6/42 Progress reports primary, March, 1942, slightly smaller, April, 1942, *in statu quo* (ileostomy performed between these two dates), no report on secondaries Death, June, 1942

18 F, 53, cervix, diagnosis carcinoma, confirmed by biopsy, 1941, no secondaries Previous treatment Wertheim's hysterectomy and radium, May, 1941, no recurrence Prophylactic course of H 11 first issue May, 1941, last issue May, 1942 Progress reports no recurrence, no secondaries Death from ascending urinary infection following vesico vaginal and recto vaginal fistulae, Dec, 1945

19 M, 31, rectum, mass completely occluding lumen, secondaries in glands, diagnosis carcinoma, confirmed by biopsy (date not given), advanced, previous duration of disease, 18 months Previous treatment colostomy, Jan, 1943, general improvement until March, 1944, followed by relapse H 11 first issue 12/4/44, last issue 30/8/44 Progress reports June, 1944, thrombophlebitis of leg, Aug, 1944, phlebitis resolved, faeces passed per rectum for first time for 18 months, Sept, 1944, progress maintained, stool size of thumb passed regularly, "rapid objective and subjective improvement" Death from peritonitis following rupture of rectum, Sept, 1944

20 F, 64, breast, secondaries in sigmoid, bladder, liver (July, 1942), diagnosis carcinoma (Broder's grade III), confirmed by biopsy, 1939, previous duration of disease and size of tumours not stated Previous treatment radical amputation, Dec, 1939, ? recurrence H 11 first issue 28/6/44, death 28/9/44 Progress reports Aug, 1944, secondaries "seem smaller", Sept, 1944, primary, *in statu quo* Death, Sept, 1944

21 M, 49, bronchus, no secondaries, diagnosis carcinoma, no report of a radiological examination, previous duration of disease and size of tumour not stated Previous treatment, none H 11 first issue 11/10/44, treatment ceased 1/3/45 (with one month interval in Jan, 1945) Progress report, March, 1945, "Clinically much smaller" Death from haemoptysis, May, 1945

22 F, 68, cervix, invading bladder, diagnosis carcinoma, grade III, advanced, inoperable, 1941, no biopsy, previous duration of disease and size of tumour not stated Previous treatment, none, too advanced for radium, 1941 H 11 first issue 10/1/42, treatment ceased June, 1942 Progress reports Jan, 1942, no vaginal examination because of "danger of haemorrhage", May, 1942, no haemorrhage after vaginal examination, growth therefore presumed to have regressed, June, 1942, suitable for radium (two applications given) Last heard of, Aug, 1946, well

23 F, 70, rectum, mass size of fist, no stricture, multiple diverticulitis, no secondaries, diagnosis ? carcinoma, no biopsy, but laparotomy, 1943, the surgeon "and a colleague" considered the growth to be malignant, but stated that "proof whether malignant or inflammatory not possible", previous duration of disease not stated Previous treatment, colostomy, Jan, 1943 H 11 first issue 1/2/43, last issue 14/2/44 Progress reports March, 1943, smaller, May, 1943, smaller, size of chestnut, July, 1943, smaller and softer, Jan, 1944, only a little thickening, July, 1946, *in statu quo* Last heard of, July, 1946, well

24 F, age not given, lung, diagnosis carcinoma, no report of a radiological examination, previous duration of disease and size of tumour not stated H 11 first issue 26/8/41, last issue 27/8/42 Progress report, April, 1942 general condition much improved, gain of 2 st (12.7 kg) in weight, no reference made to growth Last heard of, Nov, 1944, well

25 F, 40, cervix, ? secondary in lumbar glands, diagnosis primary carcinoma, prognosis one year or ? many years, no report of a biopsy on cervix or glands, previous duration of disease and size of tumour not stated Previous treatment radium, Oct, 1944, result, Jan, 1945, primary had apparently disappeared, no recurrence, radiotherapist doubtful of diagnosis of malignancy in the persisting enlarged glands H 11 first issue 10/3/45 last issue 2/11/45 Progress reports May, 1945, oedema left leg (due ? to phlebitis, ? to pressure of glands), subsided Oct, 1945, "Disease appears to be arrested", Dec, 1945, x ray report no sign of any active secondaries, no sign of malignancy Last heard of, Dec, 1945

### APPENDIX 2

Report to the H 11 Committee of the Medical Research Council on experiments performed by Dr G M Bonser in the Department of Experimental Pathology and Cancer Research, University of Leeds, designed to test the growth inhibiting properties of the extract H 11 supplied by the Hosa Laboratories.

Following the request of the H 11 Committee that I should investigate the growth inhibiting properties of H 11, it was decided that I should visit the Hosa Laboratories in order to

TABLE I—Summary of Grafting of Twort Carcinoma

Source of Grafts	Mice Grafted at Leeds		No of Takes	No of Spontaneous Regressions	Remarks
	Type	No			
First tumour from Hosa Laboratories	White label	24	0	0	All mice died within two days
Second tumour from Hosa Laboratories	White label	37	20	11	Tumour died out at 4th generation Tumour died out at 8th generation Generations 4-6 were used for experiments 1-5
Second generation in white label mice of second tumour from Hosa Laboratories	Leeds stock	360	171*	79	
Third tumour from Hosa Laboratories	(a) Leeds stock	150	80	46	Tumour discarded at 8th generation Tumour died out at 4th generation
	(b) Leeds stock	47	18	8	
Fourth tumour from Hosa Laboratories	(a) Leeds stock	8	4	2	Tumour died out at 3rd generation
	(b) Leeds stock	36	25	14	
Total		662	318*	160	

\* 50 of these mice were treated with H 11 regressions among these mice are not included in the next column  
Note—The mice were bred in the laboratory

I see for myself the exact conditions recommended to obtain the maximum experimental effect. At this visit the details of procedure were explained to me by Mr Thompson and his assistant, and plans were made to start the work at once. At the same time I pointed out that I should not regard the investigation as complete unless experiments were made with a homologous tumour transplanted into inbred mice in addition to those with the Twort mammary carcinoma, which is the only test tumour in use at the Hosa Laboratories. Mr Thompson agreed to this procedure, but expressed the opinion that it would be necessary to find out the optimum dosage required to inhibit any tumour other than the Twort carcinoma.

#### Attempts to Obtain Suitable Grafted Twort Carcinomas

1 After my visit to the Hosa Laboratories in August, 1945, I brought three mice bearing grafted Twort carcinomas back to Leeds. The 24 mice which received grafts from one of these tumours all died within a short period, this was thought to be due to an infection grafted with the tumours. The host mice, chosen after discussion with Mr Thompson, were pure-line "white label" mice, originally given to me by Dr Krcyberg (Oslo).

2 Later in the same month three more tumour-bearing mice were sent from the Hosa Laboratories. Grafts were made into "white label" mice and were maintained for four generations, when the tumour was obviously about to be lost. For this reason grafts were made from generation 2 of "white label" mice to our own laboratory mixed stock and were maintained for eight generations, when the tumour died out. Mice of generations 4, 5, and 6 were used for testing H 11. Of 360 mice grafted only 171 takes were obtained, and many of these tumours regressed spontaneously.

3 In July, 1946, four Twort-bearing mice were sent from the Hosa Laboratories. Grafts from two of these were made into stock mice. One tumour died out at the fourth generation, the other reached the eighth generation and was then discarded.

4 In December, 1946, two Twort-bearing mice were received from the Hosa Laboratories. These tumours were maintained for a few generations and were then discarded.

A summary of the graftings is given in Table I. I would emphasize the difficulties of working with this tumour, from which less than 50% of takes can be obtained. In these takes regression is very frequent (approximately 50%). The tumours which do grow to a large size are usually mere bags of fluid, with cystic necrotic centres. The more rapidly growing the tumour the more likely is the centre to be cystic. Proof that the type of mouse used was suitable as a host was forthcoming from an experiment in which 96 similar stock mice were grafted with mammary cancer M 63. Eighty-six takes were obtained, of which three tumours regressed and the rest grew progressively and rapidly.

#### Results of Five Experiments in which Grafted Twort Carcinomas were Treated with H 11

The conditions recommended by Mr Thompson were rigidly followed. (1) The tumour from which the grafts were made was allowed to grow to an optimum size of approximately

20 by 20 mm. Tumours which had caused skin ulceration were discarded. (2) The tissue for grafting was taken from the non-necrotic periphery of the tumour, each graft measured approximately 2 by 2 mm. The grafts were made subcutaneously into the flank. (3) The criterion of suitable growth of the grafts was that they should double their size in seven days, attaining a size of approximately 5 by 5 mm before treatment began. Usually the tumours were single, but a few were formed by fusion of two separate masses. (4) The mice used were young adults of either sex, pregnant mice were discarded. (5) The injections of H 11 were made into the peritoneal cavity twice daily at approximately 9 a.m. and 5 p.m. On two occasions only (one evening and the following morning) were injections not given. (6) The tumours were measured in two dimensions with mm callipers once a week.

The results of five experiments (Nos 1-5), comprising in all 50 experimental and 58 control mice, are summarized in Table II. The treatment consisted in the administration of

TABLE II—Summary of H 11 Treatment for One Month of Twort Carcinoma (grafted) in Five Experiments (Nos 1-5)

$\frac{a \times b'}{a \times b}$	$\frac{a \times b}{a \times b'}$		Rate of Growth
	Experimental	Control	
Disappeared	22	36	Complete regression
<1	7*	11†	Partial regression
1.0-1.49	2*	3*	Slow growing

9.0-9.49	1		
15.0-15.49	1		
Total mice	50	58	

\* One mouse of each of these groups had three weeks of treatment or observation only.

† Two mice of this group had three weeks of observation only.

$a \times b$  = Measurement at start

$a \times b'$  = Measurement at four weeks

the standard dose of 0.5 ml of H 11 intraperitoneally twice daily for four weeks, at which time all the surviving mice were killed. In spite of the large dose the mice stood the injections well. The index  $\frac{\text{area at 4 weeks}}{\text{area at start}}$  was calculated (Table II, column 1) and used to express five rates of growth (column 4). Complete regression of the control tumours occurred in 36 of 58 mice. This in itself is sufficient evidence that this particular

tumour is not suitable for assessing the growth inhibitory powers of a test substance. It will be noted (column 2) that there were 13 rapidly growing tumours in the treated group as against 3 such tumours in the control group. The general conclusion is that the tumours grew rather better in the treated than in the control group.

#### Use of Another Type of Grafted Tumour to Test H 11

The tumour chosen was a spindle cell sarcoma growing in a highly inbred strain of mice kept in the laboratory (CBA). (a) Grafts of this tumour rarely fail to take, and therefore it was thought that it would not be difficult to get a large number of suitable tumours. (b) The growth rate of the grafts is rapid and continuous. (c) These mice breed readily and quickly and are robust. (d) The treatment of a sarcoma would make a useful contrast to the treatment of a carcinoma, although it was realized that sarcomata are usually more resistant to growth-inhibiting substances than carcinomata. (e) As pointed out by Gye *et al* (1943) there are advantages in treating a homologous tumour in inbred mice.

It was decided to use the same dosage and method of administration of H 11 as was claimed by Hosa Laboratories to be inhibitory for the Twort carcinoma for the following reasons: (1) From the experience gained in experiment 1 it was unlikely that the mice would tolerate doses larger than 7 ml per week for four weeks. (2) It did not seem advisable to reduce the dose until an inhibitory effect had been demonstrated with the maximum dose. (3) No evidence could be found that chemotherapeutic substances act only at an optimum concentration and volume specific for each type of tumour. (4) In the treatment of human cancer of all types H 11 is first administered in arbitrary dosage of 12.5 ml per week. Some adjustment of this dose may be advised if certain reactions are observed (Ollerenshaw, 1946). Even allowing for the known fact that animals require larger chemotherapeutic dosage than man, the Hosa standard mouse dose is overwhelmingly larger weight for weight than that for man.

#### Results of Two Experiments in which Grafted Spindle-cell Sarcomata in CBA Mice were treated with H 11

**Experiment 2B**—Groups of 34 experimental and 33 control grafted tumours, averaging 7 by 8 mm after 20 days growth, were available for testing. During the second and third weeks of treatment with H 11 it was noticed that many of the mice suffered from convulsions immediately after the injection, and by the end of the third week 22 animals had died from peritonitis with or without pleurisy. This was attributed to the toxic effect of this batch of H 11, as during the same period only three of the control animals died. Six mice completed the full course of treatment and in these animals the tumours were growing with great rapidity. No conclusion in regard to the growth-inhibitory effect of H 11 could thus be drawn from this experiment.

**Experiment 6**—Groups of 43 experimental and 40 control grafted tumours, averaging 5 by 7 mm after 20 days growth, were available for testing. The standard dose of H 11 was

administered to the experimental mice for one month at which time the 40 surviving animals were killed. Regular growth of both experimental and control tumours was observed throughout the period of treatment and a statistical analysis of the rate of growth was made by Dr W J Martin (Table III). Three methods were used for estimating the growth rate of a solid tumour when two of the three diameters (designated  $a$  and  $b$ ) are known.

(1) **Volume**—Blum (1943) based his formula on the assumption that the volume of a tumour could be approximated to by a spheroid. Simplifying this formula, the value  $\log a \cdot b - \log ab$  may be calculated where  $a$  and  $b$  are the two diameters at the beginning of the experiment and  $a \times b$  the same diameters after a period of time.

(2) **Area**— $a \times b$  was used as a measure of the area, which is proportional to the area of an ellipse with diameters  $a$  and  $b$ . The Hosa Laboratories use this quotient, which is proportional to that found by method 1.

(3) **Linear**—The actual measurements of the minor and major axes were used separately. These measure linear growth and are proportional to Blum's formula when only one diameter is given.

In analysing the data certain approximations were adopted where the measurement of the axes was not entirely straightforward. (1) Five experimental and two control tumours, so small at the beginning of the experiment that accurate measurement was not possible, were assigned the measurements 3 by 3 mm. (2) Four experimental and three control tumours which at some period of growth appeared in two parts and later fused were treated as one tumour. (3) Measurements of three experimental and two control tumours in mice which failed to survive the experimental period by three days are included in the analysis, the measurement at death being taken as the measurement on the last day of the experiment.

Table III shows the size of the tumours on the first day of treatment (column 3), the weekly differences in growth (columns 4-7) and the differences over the whole four weeks (column 8). It is to be noted that the average size of the tumours on the first day of treatment did not differ between the treated and the control series. Furthermore there are no significant differences between the weekly growths of the control and experimental animals for each of the four weeks, or for the total growth during the four weeks. The tumours did not grow at a uniform rate as for both series there was a spurt during the third and fourth weeks.

The conclusion to be drawn is that there is no evidence that treatment with maximum doses of H 11 had any effect on the growth of a spindle-cell sarcoma grafted in homologous mice.

#### Use of Spontaneous Mammary Cancers in Inbred Mice to Test H 11

This type of tumour is the counterpart of human breast cancer, is easily observable, and happened to be readily available when the experiment was planned. The standard dose of H 11 (0.5 ml twice daily into the peritoneal cavity for one month) was adopted. In these mice observation was made of the growth rate of the tumours, of the appearance of new tumours, and of the occurrence of metastases.

**1 Effect of H 11 upon the Growth Rate of Spontaneous Mammary Cancer**—The size of the tumours before treatment ranged from 5 by

TABLE III—Treatment by H 11 of Spindle cell Sarcoma Growing in CBA Mice (Experiment 6) Analysis by Dr Martin (43 experimental and 40 control animals)

Measurement of Growth		Size of Tumour at Start of Experiment	Differences between Size				
			1st week/1st day	2nd week/1st week	3rd week/2nd week	4th week/3rd week	4th week/1st day
Log $ab$	Controls	1.51 $\pm$ 0.05	0.37 $\pm$ 0.03	0.28 $\pm$ 0.02	0.13 $\pm$ 0.02	0.27 $\pm$ 0.02	1.04 $\pm$ 0.02
	Experimental	1.49 $\pm$ 0.03	0.30 $\pm$ 0.02	0.32 $\pm$ 0.02	0.13 $\pm$ 0.01	0.29 $\pm$ 0.02	1.04 $\pm$ 0.03
	Controls/Exp	0.02 $\pm$ 0.06	0.07 $\pm$ 0.04	-0.04 $\pm$ 0.03	0.00 $\pm$ 0.02	-0.02 $\pm$ 0.03	0.00 $\pm$ 0.03
$a \times b$	Controls	39.7 $\pm$ 3.98	53.7 $\pm$ 6.61	104.6 $\pm$ 14.0	63.6 $\pm$ 11.9	197.3 $\pm$ 21.0	413.9 $\pm$ 43.1
	Experimental	35.0 $\pm$ 2.48	39.6 $\pm$ 4.77	83.2 $\pm$ 7.9	56.1 $\pm$ 5.9	188.4 $\pm$ 19.3	363.4 $\pm$ 31.1
	Controls/Exp	4.7 $\pm$ 4.7	14.1 $\pm$ 8.2	21.4 $\pm$ 16.1	7.5 $\pm$ 13.3	8.9 $\pm$ 28.5	50.5 $\pm$ 53.1
Major axis	Controls	6.55 $\pm$ 0.37	3.68 $\pm$ 0.31	4.53 $\pm$ 0.49	2.33 $\pm$ 0.37	6.13 $\pm$ 0.46	16.54 $\pm$ 1.16
	Experimental	6.05 $\pm$ 0.24	2.86 $\pm$ 0.30	4.44 $\pm$ 0.33	2.58 $\pm$ 0.23	6.19 $\pm$ 0.40	16.00 $\pm$ 0.91
	Controls/Exp	0.50 $\pm$ 0.44	0.82 $\pm$ 0.43	0.09 $\pm$ 0.59	-0.25 $\pm$ 0.44	-0.06 $\pm$ 0.61	0.54 $\pm$ 1.47
Minor axis	Controls	5.53 $\pm$ 0.25	2.83 $\pm$ 0.22	3.20 $\pm$ 0.32	1.70 $\pm$ 0.21	4.33 $\pm$ 0.34	11.92 $\pm$ 0.77
	Experimental	5.9 $\pm$ 0.18	2.23 $\pm$ 0.22	3.14 $\pm$ 0.24	1.51 $\pm$ 0.22	4.52 $\pm$ 0.34	11.32 $\pm$ 0.63
	Controls/Exp	0.04 $\pm$ 0.31	0.60 $\pm$ 0.31	0.06 $\pm$ 0.40	0.19 $\pm$ 0.30	-0.19 $\pm$ 0.47	0.60 $\pm$ 0.47

6 mm to 17 by 17 mm, a range inevitably much greater than in a group of grafted tumours. The growth rate was estimated by calculating the index  $\frac{a \times b'}{a \times b}$  (Table IV). Twenty eight tumours in

animals bearing palpable tumours at the beginning of the experiment were rejected the following figures for mean growths would be obtained

*Average Size on First Day of Treatment ( $a \times b$ )*

	Controls	Treated	Difference
All observations	39.7	35.0	$4.7 \pm 4.7$
Omitting palpable tumours	44.1	36.2	$7.9 \pm 4.7$

Thus the omission of the palpable tumours gives a group of treated tumours which were rather smaller at the beginning of the experiment than the controls

At the end of the first and third weeks the following figures are obtained

	Average Increase in Size between the First Day and the First and Third Weeks ( $a \times b$ )					
	First Week			Third Week		
	Treated	Con- trols	Difference	Treated	Con- trols	Difference
All observations	39.6	53.7	$14.1 \pm 8.2$	178.9	221.9	$43.0 \pm 32.9$
Mr Thompson's results	40	57.5	17.5	181	244	63.0
Omitting palpable tumours	41.1	57.7	$16.6 \pm 8.6$	184.3	243.8	$59.5 \pm 33.1$

Thus at the end of the first week the difference between the two groups when all the observations are included is not significant, when the palpable tumours are omitted the P value is  $>0.05$ , but according to Mr Thompson's calculations the P value is  $<0.05$ . Taking into account the fact that the treated tumours in the selected group of mice were rather smaller at the beginning of the experiment than the controls, there is no evidence that growth was actually inhibited by the treatment during the first week.

The question arises whether the experiments were suitably planned to demonstrate the growth-inhibitory action of a chemotherapeutic substance. The five experiments in which grafted Twort carcinomata were used obviously gave no conclusive answer because of the high regression rate in the control series. Difficulties were also encountered in propagating this tumour many grafts failing to take and regressions being frequent (Table I). Experiment 6, using a spindle cell sarcoma growing in homologous mice, was satisfactory with regard to survival and numbers, but it might be argued that this was likely to be a resistant tumour and therefore not suitable for such a test. The final experiment using spontaneous mammary cancer in inbred mice would appear to have been satisfactory from all points of view, and it, also, failed to demonstrate growth-inhibitory properties in H 11.

As it was thought advisable to confirm these findings in a more extended series of experiments, a request was made to the Hosa Laboratories for further supplies of H 11 to be used as follows: (1) To test the M 63 mammary carcinoma grafted in stock mice a tumour known to be easily propagated and with a low regression rate. This was the tumour used by Gye *et al* when they tested H 11. (2) To test a mammary carcinoma grafted in homologous mice of the C3H strain. There is good evidence that trials of chemotherapeutic substances are more reliable when made upon homologous transplanted tumours. (3) To control the above test more rigidly by the use of groups of mice (a) injected intraperitoneally with saline only, and (b) treated with urethane, a known tumour inhibitor.

TABLE IV—Summary of Growth Rates of Spontaneous Mammary Cancer in Inbred Mice

$\frac{a \times b}{a \times b'}$	Treated	Un- treated	Rate of Growth	Percentage of Treated	Percentage of Untreated
Disappeared	—	—	Complete regression	—	—
$< 1$	—	—	Partial regression	—	—
1.0–1.49 1.5–1.99	2 3*	1 3	Slowly growing	17.9	23.5
2.0–2.49 2.5–2.99 3.0–3.49 3.5–3.99	10* 3 4 —	3 1 4 1	Moderately growing	60.7	52.9
4.0–4.49 4.5–4.99 5.0–5.49 5.5–5.99 6.0–6.49 6.5–6.99 > 7.0	1 — 2 1 1 1 —	1 — — 2 — — 1	Quickly growing	21.4	23.5
Total tumours	28	17			

\* One mouse failed to complete the month of treatment by four days

23 mice were treated for one month,\* and it is to be noted that not one tumour regressed or disappeared. In fact, the great majority grew either moderately or quickly. The growth rates of 17 similar untreated tumours in 15 mice were observed. There was a striking similarity of growth rate in the two groups, any slight difference was on the side of a rather more rapid rate in the treated tumours.

2. *Appearance of New Tumours*—In the treated and control groups, 8 and 5 new tumours appeared respectively in other breasts. It would thus appear that treatment with H 11 was not inhibitory in this regard.

3. *Occurrence of Metastases*—Metastases in the lung occurred in one treated mouse but were not observed in the control series.

### Discussion

Using three types of test tumour—grafted carcinoma in stock mice, grafted sarcoma in homologous mice, and spontaneous mammary carcinoma in susceptible inbred strains—it has not been possible to demonstrate a growth-inhibitory action of H 11. At the request of the Hosa Laboratories the tumour measurements in experiment 6 were submitted to Mr Thompson for statistical analysis.

Dr Martin had found that there was no difference between the two groups in any week of the experiment, whereas Mr Thompson found that there was a 30% inhibition of growth (regarded as significant) in the treated animals in the first week. There was no significant inhibition in the second, third, and fourth weeks (Table V).

This difference of analysis could be explained as follows. Dr Martin included all the animals—i.e., 40 controls and 43 treated—accepting a measurement of 3 by 3 mm for palpable tumours which were too small to measure accurately. Mr Thompson, however, rejected five control and two experimental animals for reasons unstated. If a guess is made that those

\* Two mice failed to complete the month of treatment by four days

TABLE V—Experiment 6 Spindle cell Sarcoma Growing in CBA Mice 1 ml H 11 Injected Daily Analysis by Mr Thompson

Weeks	35 Mice Untreated			41 Mice Treated with H 11			Difference Between the Means (mm)	Significance of the Difference (P)	Inhibition (%)
	Mean Growth (mm)	Variance	Standard Error	Mean Growth (mm)	Variance	Standard Error			
1	57.5	41	6.4	40.0	25	5.0	17.5	$<0.05$	30
2	172.0	462	21.5	127.0	151	12.3	45.0	$>0.05$	26
3	244.0	983	31.3	181.0	244	15.6	63.0	$>0.05$	26
4*	455.7	2040	45.2	376.7	1044	32.3	79.0	$<0.20$	17

\* 39 treated, 34 non treated

Notes—P factor is fully significant for the 1st week, probably significant in the 2nd and 3rd weeks and without significance in the 4th week. The standard error is high after the first week. Only in the 1st week of the experiments are the various data fully significant.

This request was refused, and the experiments were therefore terminated. The refusal was based upon the contention that unless preliminary experiments were undertaken to test the effects of optimum volume and concentration of H 11 upon M 63 and C 3H tumours the results would be valueless. After considerable thought had been given to this suggestion it was decided that no useful purpose would be served by undertaking dosage experiments.

### Summary

Evidence is presented that grafted Twort mammary carcinoma is not a satisfactory tumour upon which to test a chemotherapeutic substance for growth inhibitory properties. This statement is based upon extensive attempts to propagate this tumour, which often does not take and has a high regression rate (Table I).

No growth inhibiting effect of H 11 could be demonstrated in experiments in which grafted Twort carcinoma was the test tumour (Table II) nor in experiments in which a grafted spindle cell sarcoma in homologous mice was tested (Table III).

H 11 had no effect on the growth rate of spontaneous mammary cancer in inbred mice as compared with that of similar untreated tumours (Table IV). New tumours were not prevented from arising, and metastasis took place in spite of the treatment.

Grateful acknowledgment is due to Dr E. C. Armstrong and Dr W. J. Martin to the former for much help in propagating the grafted tumours and in administering the H 11 treatment, to the latter for the statistical analysis of the experiments.

## DEFICIENCY OF VITAMIN A IN UNIVERSITY STUDENTS

BY

STELLA DORAISWAMI, B.Sc. Madras

AND

JOHN YUDKIN, M.A., M.D., Ph.D., F.R.I.C.

(From Kings College of Household and Social Science  
University of London)

In spite of the intense current interest in the nutritional state of the people of this country there are few positive data from which it is possible to draw any very definite conclusion (see *Lancet* 1948). It might therefore be of interest to describe the results of a recent investigation which suggests that about one-fifth of a group of university women students are deficient in vitamin A.

### Dark-adaptation and the Effect of Vitamin A

This investigation was carried out in February and March, 1948, and consisted in the determination of the dark-adaptation of a group of students and the study of the effect upon it of vitamin A. The dark-adaptation was measured by the Crookes adaptometer (Godding, 1945). The principle of construction and the technique of use of this apparatus are similar to those of the Haines apparatus employed in previous studies (see Yudkin, 1945). The complete dark-adaptation curve was determined twice for each subject and the second curve taken as representing the true course of dark-adaptation, since it has been shown both in this and in previous investigations that any improvement due to a "learning factor" is almost, if not quite, completed in the second test.

Some of the students were then given three capsules containing 100,000 i.u. of vitamin A daily for 14 days, and others were given capsules containing arachis oil for the same time. The dark-adaptation was measured about 24

hours after the last dose by one of us (S.D.), who did not know which students had received the vitamin A or, indeed, the proportion of these students.

It has been shown that an improvement in dark adaptation is always accompanied by a decrease in the "final rod threshold" (Yudkin, Robertson, and Yudkin, 1943). We have taken as a significant improvement a decrease in this threshold of more than 0.15 log  $\mu$ l (micromicrolamberts). None of the 19 control subjects in this investigation showed any improvement after the administration of the capsules containing arachis oil. Of the 46 subjects given vitamin A, seven showed a significant improvement of dark-adaptation. Of a smaller series of six postgraduate students given 200,000 i.u. of the vitamin daily for eight days, two showed a significant improvement (Table I).

TABLE I—Effect of Vitamin A on the 'Final Rod Threshold' of 52 Students

Effect of Vitamin A on Threshold	No. of Students
Increase of 0–0.15 log $\mu$ l	3
No change	13
Decrease of 0–0.15 log $\mu$ l	27
Decrease of more than 0.15 log $\mu$ l — i.e. significant improvement	9

### Dietary Intake of Vitamin A

The studies of dark-adaptation suggest that nearly one-fifth of the students were deficient in vitamin A. It is of interest, then, to know something of their dietary intake of the vitamin. It has not been possible to determine this for all the students whose dark-adaptation has been measured, but we have some information about the diets of other students, both resident and non-resident, of the same college.

It is the practice here for the postgraduate dietetic students, who are not in residence, to record by weighing their own intake of food for one week in October. Records of 14 students were kept in 1946 and 1947. The composition of the foods eaten was assessed by reference to the tables (M.R.C., 1945a). The values for carotene were divided by three, the commonly accepted factor, in order to convert them into equivalents of vitamin A. Of the 14 students, three had an average daily intake of less than 2,500 i.u. of vitamin A, seven an intake of between 2,500 and 5,000 i.u., and four an intake of more than 5,000 i.u.

The dietary intakes were also recorded of 20 first year residential students during November, 1947. The data were collected by dietetic students for an investigation carried out by Dr Magnus Pyke and Miss K. Chamberlain, of the Ministry of Food. The total amount of food consumed by the students was recorded for a week by the "matching" method, and in addition the food of three meals each day, comprising about one-half of the total intake, was recorded by the "weighing" method. Since the latter method is the more accurate we have assessed the intake of vitamin A by a combination of the two methods, adding the intake of the three meals as determined by the weighing method to that of the rest of the food as determined by the matching method. Of the 20 students, four had an average daily intake below 2,500 i.u. daily, 14 an intake between 2,500 and 5,000 i.u., and two an intake of more than 5,000 i.u. Table II summarizes the dietary intake of vitamin A for the total of 34 students of both groups.

TABLE II—Average Daily Intake of Vitamin A by 34 Students

Average Daily Intake	No. of Students
Below 2,500 i.u.	7
Between 2,500 and 5,000 i.u.	21
More than 5,000 i.u.	6

There is reason to believe that 2,500 iu of vitamin A represents, as nearly as can be ascertained, the average minimal daily requirements of the vitamin for young adults. It is of interest, therefore, that the proportion of students whose consumption of vitamin A was below 2,500 iu daily is very similar to the proportion whose dark-adaptation improved with vitamin A (7 out of 34, or 21%, and 9 out of 52, or 17%).

Since nearly all the preformed vitamin A in the diet is derived from rationed foods—butter, margarine, cheese, and milk—it is interesting to see how much vitamin was consumed by the students. At the times of the surveys the rations of these foods contained between 1,000 and 1,100 iu of the vitamin daily. Of the 34 students whose diets were examined, the intake of preformed vitamin A from these foods was between 700 iu and 4,000 iu daily—mean 1,700 iu. Thirty of the students consumed more than the 1,100 iu daily to which their rations entitled them. We do not wish to comment on this beyond pointing out the relevance of such findings to recent rather heated discussions which attempt to evaluate accurately the probable intake of nutrients from a study of the foods theoretically available from the rations.

The remainder of the vitamin A consumed was almost entirely in the form of the provitamin carotene. Assuming again that carotene has one-third of the activity of preformed vitamin A, the intake was between 750 and 4,000 iu daily—mean 1,850 iu. The proportion of the preformed vitamin A to the total intake was between 22% and 79%. It is perhaps not surprising that the range of intake of vitamin A and of carotene was larger in the group of non-resident students (Table III).

TABLE III—Average Daily Intake of Preformed Vitamin A and of Carotene

Group	Total A (i u)	Preformed A (i u)	Carotene (i u)	Proportion of Preformed A
20 residents	1 650-4 900 (3 450)	700-2 950 (1 600)	950-3 000 (1 850)	31-67% (46%)
14 non residents	2 300-6 650 (3 750)	900-4 000 (1 900)	750-4 000 (1 850)	22-79% (51%)
Total	1 650-6 650 (3 550)	700-4 000 (1 700)	750-4 000 (1 850)	22-79% (48%)

### Correlation of Dark-adaptation and Intake of Vitamin A

Thirteen of the students took part in the two investigations described, so that data are available for each of them both of their intake of the vitamin and of the effect of vitamin A upon their dark-adaptation. Three of these had intakes of vitamin A of less than 2,500 iu daily, each of these three, and no others, showed a significant improvement of dark-adaptation following administration of vitamin A (Table IV).

TABLE IV—Correlation between Vitamin A Labile Dark-adaptation and Dietary Intake of Vitamin A

Subject	Daily Intake of Vitamin A (i u)	Effect of Supplements of Vitamin A on Dark adaptation
47	6 650	—
42	5 650	—
5	4 900	—
4	4 350	—
19	4 050	—
46	3 750	—
44	3 450	—
9	3 050	—
16	3 050	—
6	3 000	—
48	2 450	—
11	2 400	+
43	2,300	+

+ Indicates a decrease of more than 0.15 log  $\mu$ l in the final rod threshold. Subjects 42-47 were non resident; the remainder were resident in college.

## Discussion

### Requirements of Vitamin A

It should be stressed at once that the determination of the requirements of any nutrient is a much more complex matter than is usually realized. There has been a tendency to suppose that it is possible to stipulate a definite amount of a nutrient, a consumption below this amount leading inevitably to a state of deficiency and above it to a state of optimal nutrition in respect of that nutrient. This attitude is quite unrealistic for many reasons, which have been discussed in some detail elsewhere (Yudkin, 1948). Two aspects in particular concern us here. The first is that there is undoubtedly with many nutrients, and probably with all, a range of intake between the minimal, which is necessary to prevent frank deficiency disease, and the optimal, beyond which no improvement in any respect will occur. Whereas it may be comparatively easy to determine the former, since below it obvious signs will develop, it may be extremely difficult to determine the latter, since increasing amounts of the nutrient may produce such ill-defined effects as increased resistance to infection or increased general well-being.

The second important difficulty in determining requirements is that there are differences between various individuals even of the same sex and age, and also differences in the same individual at different times. One cannot therefore suggest an amount of a nutrient as the requirement for, say, young women and assume that any one of them consuming less than this would necessarily be receiving an insufficiency and any one consuming more would necessarily be receiving a sufficiency.

With these considerations in mind, we must conclude that it is only within fairly wide limits that we can ascertain what the requirements of vitamin A are for such subjects as we have examined. First, if we know just how much vitamin A will prevent a deterioration of dark-adaptation we cannot assume that this amount will be adequate for all other physiological functions. Secondly if we find that 2,500 iu of vitamin A daily will just prevent a deterioration of dark-adaptation in one individual it is more than likely that higher or lower amounts will be necessary for other individuals.

An examination of the published work confirms these conclusions. Callison and her colleagues studied in young adults the effect on dark-adaptation of diets deficient in vitamin A, to which was then added vitamin A or carotene (Booher and Callison, 1939; Booher, Callison, and Hewston, 1939; Callison and Orent-Keiles, 1947). The carotene was given either as the pure provitamin in oil or in its natural state in vegetables. The amount of vitamin A required to restore normal dark-adaptation was between 1,300 and 3,900 iu (mean 2,400) and of carotene in oil between 2,200 and 7,200 iu (mean 4,300) daily for five subjects. They found that carotene was less well utilized from oily solution than from spinach and peas, but better than from carrots.

A subcommittee of the Medical Research Council (M.R.C., 1945b) reported that in three subjects 1,300 iu of vitamin A or 2,600 iu of carotene in oil daily restored normal dark-adaptation of subjects on a diet deficient in the vitamins. Unlike the American workers, they found that carotene is less well absorbed and hence presumably less well utilized from spinach, as well as from cabbage and carrots, than it is from oily solution.

Since the subjects in these investigations were on special diets and it is known that other dietary components affect requirements, and since it is commonly held that, in

general, carotene is not so effectively absorbed from vegetables as from solutions in oil, it is likely that more vitamin A is needed in normal diets than the amounts suggested by the M R C subcommittee

Our results show that, in a small number of subjects, dark-adaptation was apparently normal in 10 subjects consuming more than 3,000 i.u. of vitamin A daily and abnormal in three consuming less than 2,500 i.u. It should be emphasized that these figures include variable amounts of carotene, which has been assumed to have an activity in the human being of one-third that of vitamin A. Since this value is not accurately known, but varies both with the subject and with different types of food, and since the number of subjects is small, we do not wish to overestimate the importance of our findings in this respect. We would only justify this discussion about the relevance of our findings to the requirements of vitamin A by pointing out that, unlike previous work, our data refer to subjects on a normal diet, and that such correlative studies of physiological function and dietary intake clearly offer a most important means of gaining knowledge of requirements. We hope it will be possible to carry out observations of this nature on a much more extensive scale.

#### Previous Studies

It would have been of great interest if we had been able to compare the data presented here with similar evidence of deficiency of vitamin A obtained in previous years. There exists unfortunately very little work of a similar sort referring to conditions in this country. Most of the work which does exist relates to estimations of vitamin A in the blood or in the liver, where standards of normality are not yet agreed. As regards dark-adaptation, very few previous reports include studies of the effect of vitamin A. In a series of 335 factory workers in whom only the "final" rod threshold was measured, the proportion which showed improvement after supplementation with 5,000 i.u. daily for eight months was significantly greater than the proportion in the control subjects—73 out of 147 (50%) compared with 58 out of 188 (31%) (Yudkin, 1944). In 320 school-children, on the other hand, studies involving determination of "final" rod threshold or of the complete course of dark-adaptation showed that no improvement followed the administration of vitamin A (Robertson and Yudkin, 1944). In a small series of adults, studied intensively in the way described in the present report, six out of a total of 14 given vitamin A or carotene showed an improvement in dark-adaptation in which the "final" rod threshold decreased by more than 0.15 log  $\mu\text{l}$  (Yudkin, Robertson, and Yudkin, 1943). In another small series of 15 Army officers, studied in the same way in the winter of 1944-5 by one of us (J.Y.), none showed a significant change in the course of dark-adaptation following large supplements of vitamin A. This may well have been due to the appreciably higher amount of vitamin A in Army rations than in civilian rations. For example, the chief sources of preformed vitamin A—butter, margarine, cheese, and milk—supplied between 1,500 and 1,600 i.u. daily in the Army rations and between 1,000 and 1,100 i.u. daily in the civilian rations.

It seems then, that, on the basis of improvement of dark-adaptation following administration of vitamin A, deficiency of the vitamin among civilian adults is not a new phenomenon. It is unfortunately impossible to answer adequately the important question whether there has been any increase or decrease in the proportion with this deficiency. This of course does not make it any the less disturbing that as many as one-fifth of a sample of young adult women should show deficiency of vitamin A at the present time.

#### Significance of Impaired Dark Adaptation

There are two attitudes one might adopt towards the findings that about one-fifth of our subjects have a dark adaptation which improves with vitamin A. One is that, since dark-adaptation is a normal function of the body, any impairment in it which can be improved by vitamin A must be taken as indicating that the physiological demands of the vitamin have not been met. It is indeed possible that other functions not so readily investigated are also affected. Moreover, even if the intake of the vitamin is sufficient just to restore dark-adaptation, one cannot assume that such other functions are also restored. The second attitude one might adopt is that dark-adaptation is not a very important physiological function anyway, so that a slight impairment is of little practical consequence and need not cause any concern about the adequacy of the diet. We can say at once that we believe this attitude to be quite untenable. We would stress that most of the methods which are used to determine the probable state of nutrition of individuals, such as the determination of levels of nutrients in the blood or in the urine, involve many assumptions in their interpretation, here, on the other hand, we are concerned with the measurement of a normal physiological activity of the body. If we find that such an activity is in one fifth of a population adversely affected by the diets they consume we must consider that the situation is far from satisfactory.

#### Summary

The course of dark adaptation of 52 women university students was measured and the effect of supplements of vitamin A observed. Nine showed a significant improvement of dark adaptation—that is a decrease of more than 0.15 log  $\mu\text{l}$  in the "final" rod threshold.

A study of the dietary intakes of 34 students showed that the average daily intake of seven of them was below the probable average requirement of 2,500 i.u. daily. Thus both the measurement of dark adaptation and the assessment of the dietary intake of the vitamin reveal a similar proportion of subjects (about 20%) who were probably consuming a diet deficient in vitamin A.

Of the 13 students for whom measurements of both dark adaptation and dietary intake were available the three whose average daily intake of vitamin A was below 2,500 i.u. were the only three whose dark-adaptation improved with vitamin A.

It is impossible to say whether the proportion of deficient subjects has been influenced by recent dietary restrictions but the fact that something like 20% of women university students are deficient in vitamin A is one which cannot be regarded lightly.

We are indebted to the Ministry of Food for permission to quote the results of their dietary investigation. Our thanks are also due to Crookes Laboratories for the loan of the adaptometer and the gift of capsules, and to the British Drug Houses, Ltd., and Allen and Hanburys, Ltd., for grants towards the expenses of this work.

## THE DIETARY INTAKE OF A CLASS OF STUDENTS

BY

R P COOK, MB, DSc

(From the Department of Biochemistry University College  
Dundee)

For the past two years medical, dental, and science students attending the classes in biochemistry here have measured their dietary intake over a period of one week by the log-book method. Admittedly this method is not as accurate as is the weighing method of computing the dietary, but it is simple. Moreover, it is not difficult to persuade students to make notes of the portions of food they have eaten. If the exercise is taken into account in the practical examination it is surprising how co-operative the students become!

It was possible to check, in part at least, the values obtained by measuring the nitrogen excretion on a 24-hour sample of urine. This experiment was carried out by approximately half the members of the class. The main data with regard to the participants in the experiment are as follows:

**Number and Sex** 44 males and 14 females (44 were ex-Service men and women)

**Age** 17-31 years

**Residence** 35 lived at home, 12 in university hostels, and 11 in lodgings, about 35 took their mudday meal in the University Union dining hall

**Health** All were apparently in good health

**Period of Study** The dietaries were carried out for a period of one week between the months of October and December, 1947

**Dietary intake** Each student was provided with explanatory sheets in which were given the approximate weights of portions of the commoner foodstuffs, a separate table gave the composition of portions of the commoner soups. It was recommended that butter, margarine, jam, etc., and milk be set aside as a separate daily ration. A log was kept by the student of the portions of foodstuffs served at the various meals throughout the seven days. The portions were then converted into gramme equivalents of the different foods.

**Food Tables** The values in Table I (i.e., composition of the 'edible portion' per 100 g) of 'Nutritive Values of Wartime Foods,' MRC War Memorandum No. 14, were used for the calculations.

In Table I are given the values obtained by the class. These values are contrasted with those of Widdowson (1936) for men and Widdowson and McCance (1936) for women. The standard deviation has been calculated by the method advocated by Bradford Hill (1942). No values for vitamin A are given in Table I as there was some doubt about the conversion of carotene into vitamin A units. Carrots were a popular article of diet during the period of study, and an apparent average value of approximately 10,000 iu of vitamin A a day was obtained.

**Bread** The range of consumption per week was for men 22-108 oz (624-3060 g), mean 56.4 (1599 g), for women, range 18.5-41 oz (525-1162 g), mean 28.5 (908 g).

**Potatoes** Men range per week 22.5-98 oz (636-2778 g), mean 53.6 (1520 g), women, range per week 22-62.5 oz (624-1762 g), mean 40 (1134 g).

**Nitrogen Excretion**—As a class exercise the determination of nitrogen in a 24-hour sample of urine is carried out by about half the class of medical students. The Kjeldahl method of estimation was employed, and it was

out by the students themselves, and the results, owing to inexperience with technical methods, are not of a high degree of accuracy. It will be seen that the average values obtained by multiplying either total urinary nitrogen or urea nitrogen by 6.25 are of the same order as the values for total dietary protein. It should be noted, however, that the collection of the urine samples did not necessarily coincide with the period at which the dietary was taken.

### Summary

The dietary intake of a class of university students has been determined by the logbook method. The results are summarized in Table I, which reveals considerable variation in individual intakes. Determination of nitrogen in a 24 hour sample of urine gives a value which when multiplied by 6.25 corresponds to the calculated dietary intake of protein.

## CONGENITAL OCCLUSION OF THE DUODENUM

BY

S GLASER, FRCS

*Honorary Assistant Surgeon Royal United Hospital Bath*

Duodenal obstruction in the newborn is a relatively rare lesion, though numbers of cases have been reported in the literature. The following two cases are considered of sufficient interest to merit recording.

### Case 1

A female child, aged 10 months, was admitted to hospital because of persistent vomiting. The mother stated that the patient had suffered from projectile vomiting shortly after birth until she was three months old. (The history obtained from the mother about this phase was difficult to interpret. Later inquiries from the family doctor revealed that he had treated the child for pylorospasm, as there was projectile vomiting but no tumour and that she had made slow but definite progress with medical treatment.) After the age of 3 months the vomiting had stopped and she had progressed satisfactorily. While away on holiday the child had started vomiting again, and for the last three days all feeds had been brought up. The vomiting was projectile, effortless and very forceful. The child had become very ill and the parents had terminated their holiday and rushed her home. The mother told the ward sister that the vomit had at first contained some wool which she thought might have been plucked from a shawl.

Examination revealed a desperately ill, apathetic, dehydrated child with lax skin and sunken eyes. The abdomen was fallen in and scaphoid. Peristalsis was not seen but a typical projectile vomit was observed. A tumour 1 in (2.5 cm) long was felt in the region of the pylorus. This disappeared under the fingers but was felt once more. A provisional diagnosis of pyloric stenosis was made and saline was given rectally. Next morning the general condition was slightly improved, but she was still vomiting anything given by mouth and was extremely ill. She was seen in consultation with a senior colleague. Peristalsis could not be seen and no lump could be felt and it was decided to wait. A few hours later the child died.

Necropsy revealed a large empty stomach. The proximal half of the duodenum was very distended, with thickened and hypertrophied musculature. There was an almost complete septum across the lumen of the bowel, causing the obstruction. The septum was just proximal to the opening of the bile duct which was running into the septum. The small aperture was plugged by a tangle of threads.

A sister born later has been seen since with a similar history of vomiting soon after birth but a barium meal revealed no obstructive lesion.

### Case 2

A female child aged 9 days, was sent in with a diagnosis of pyloric stenosis. The history obtained from the father was that he thought the child had been all right on the first two days but he was uncertain. He was sure, however, that from the third day she had vomited every feed, even when changed to glucose-water. The vomited material was and had been bile stained. During the last three days vomits had become projectile in character. The bowels had not been open for six days but before that meconium had been passed normally. The child was healthy very hungry and fed well, but she was losing weight. Of two older sisters one had vomited for a few days after birth.

On examination the child was found to be in surprisingly good condition slightly but not severely dehydrated. No lump could be felt in the abdomen. After a test-feed a wave of gastric peristalsis was observed and a bile-stained projectile vomit occurred. A diagnosis of congenital duodenal stenosis was made and consultation sought with a paediatrician. He agreed with the diagnosis and urged immediate surgery because of the good general condition.

Under open ether anaesthesia the abdomen was explored through a right rectus muscle splitting incision. The duodenum

was found to be obstructed across its second part by a large band. The caecum was in the region of the spleen and the small gut occupied the right part of the abdomen, the ileum entering the caecum from the right. There was no duodenal jejunal flexure, the duodenum continuing on direct into the jejunum without any bend. The constricting band appeared to contain an artery, and it was thought wiser to do a short circuit than to divide the band. An anterior gastro-jejunostomy was performed, making a stoma about 1 in (2.5 cm) long. The abdomen was closed without drainage and without making further anatomical investigations.

Post-operatively the patient's feeding was supervised by the paediatrician, it followed roughly the same routine as in the case of a congenital hypertrophic pyloric stenosis. Occasional non-projectile vomiting occurred during the first four days, but the child fed well and her bowels opened. After the fourth day she ceased vomiting and began to gain weight. A week later she was feeding well without vomiting, the bowels were open normally, and she was gaining weight. The wound was well healed and the sutures were removed. When seen again two months later she looked puny and had not been putting on weight well. There had been some difficulty with feeding, but that was improving. Her doctor wrote eight months later that the child, then 10 months old, was eating well and putting on weight. She then weighed 16 lb (7.26 kg).

### Discussion

An excellent review of the whole subject, with four case histories, has been published by Forshall (1947), and the problem is discussed in detail with a review of most of the literature. Following Ladd, cases are classified in two groups, depending on whether the obstruction is extrinsic or intrinsic. In the first group the obstruction is usually due to some abnormality of intestinal rotation, the distal duodenum being compressed by abnormal peritoneal bands or there being a volvulus of the midgut loop. The anatomical abnormality commonly found in these cases is the colon in the left abdomen, with the ileum entering the caecum from the right. In the second type of obstruction the cause may be a complete stenosis of the duodenum, a narrowing of its lumen, or a septum partially or completely occluding it. This usually occurs in the region of the ampulla of Vater. Keith (1933) points out that the lumen in this region of the duodenum is normally occluded by proliferating epithelium during the fifth and sixth weeks of embryonic life, when the liver and pancreatic buds are growing out, and that in cases of congenital occlusion of the duodenum the epithelium becomes organized instead of being absorbed.

In both groups the clinical picture is similar and characteristic. Vomiting is the main symptom and starts within a day or two of birth. It is usually bile stained, as in most cases the obstruction is below the main bile duct. The child becomes dehydrated rapidly and loses weight, and if untreated dies of inanition. Each of the above cases illustrates one of these varieties.

In Case 1 the main interest lies in the length of survival of the child. The aperture in the septum across the duodenum was large enough to take a fluid diet and the early stages of a mixed diet. The obstruction was caused finally by the blocking of the small hole by some cotton or wool. The possibility arises that many cases are undiagnosed, and it is striking that great numbers are reported from Boston (Mass.), where there is a very keen interest in congenital lesions. Many may die unrecognized, and without post-mortem examination may be wrongly certified. Furthermore, this case of incomplete septum shows how careful medical treatment carried the child over the initial obstructive stage. Some cases, like this one, survive the early stages and become obstructed later. Forshall quotes Seidlin's case of a child who died of obstruction at the age of 24 years, after eating canned corn. Balfour (1932) records the case of

a patient aged 12 on whom he operated for increasing obstruction with vomiting, and in whom the duodenum was two-thirds closed

In Case 2 the obstruction was of the extrinsic variety and showed the main characteristic features—i.e., bile-stained vomiting coming on soon after birth, loss of weight, and dehydration. At operation the colon was on the left side of the abdomen with the caecum in the region of the spleen, while the small gut was on the right side. The main interest, however, lies in the fact that the child survived the operation of gastro-jejunostomy. Forshall tabulates in her paper the previously recorded survivals after an anastomosis and reports two further cases, making in all a total of 32. Case 2 adds another to the small list.

### Summary

Two cases of duodenal obstruction in the newborn are described, one of which survived gastro-jejunostomy.

The syndrome of congenital occlusion of the duodenum is clear cut, and though rare it should be recognized when it occurs and should be diagnosed early. This is important, as the condition is amenable to surgical intervention, and, contrary to general belief, the very young infant stands up extremely well to the required major surgery.

## URETERIC CALCULUS CAUSING ANURIA

BY

NESTOR J. S. NATHAN, MRCS, DPH, DRCOG

AND

CYRIL JOSEPHS, MB, BS, DCH

(From the Stanncliffe General Hospital Dewsbury)

Anuria due to mechanical obstruction is an uncommon phenomenon. In the following case the patient had absolute anuria, which was found to be due to a calculus blocking the ureter just below the pelvis of a solitary kidney. He made a complete recovery after removal of the calculus.

### Case Report

The patient, a man aged 63, had been gassed during the 1914-18 war and subsequently had had bronchitis. In 1936 a perforated duodenal ulcer had been oversewn. He was fit until 1946, when frequency and difficulty of micturition began. In June 1946 a transurethral prostatectomy was performed. He remained unwell and lost a considerable amount of weight. He was admitted to hospital on Dec. 9, 1946, his general condition being very poor. The urine contained pus and grew a culture of *B. coli*. An intravenous pyelography showed a non-functioning right kidney. A course of sulphathiazole combined with penicillin had no effect.

On Dec. 20 the right kidney was explored by Mr. E. R. Flint. There was a large pyelonephrosis but no obvious cause could be found. The right kidney was removed. After operation the patient made an excellent recovery, the urine cleared up, and he gained weight rapidly.

On Aug. 19, 1947 he was readmitted complaining of pain in his left loin and anuria. On catheterization only 1 oz (28 ml) of urine was obtained. The urine was normal. The blood urea was 279 mg per 100 ml of blood. Anuria persisted for seven days in spite of intravenous 4.285% sodium sulphate solution, fluids, hot packs to the loin, light baths, pilocarpine, and cupping. Cystoscopy was carried out and intravenous indigo carmine given. There was no secretion from the left kidney.

A second operation was performed by Mr. E. R. Flint on Aug. 26. The left kidney was explored and freed from its bed. A stone was palpable in the ureter 3 in (7.5 cm) below the

renal pelvis. An incision was made in the ureter. There was a profuse discharge of pus, and a stone the size of a plum-stone impacted in the left ureter was removed. The ureter was drained and a superficial drain was also inserted into the wound. Eighteen hours after his return from the theatre 6 oz (170 ml) of urine was passed normally. Urine drained freely from the ureteric drain, but each day the amount of urine passed normally increased. The ureteric drain was removed on the fifth day, the wound healed, and no residual sinus occurred. The patient was discharged on Sept. 29, 1947, perfectly fit and passing urine normally.

We are indebted to Mr. E. R. Flint for permission to publish this report.

## Medical Memoranda

### Unusual Case of Twins

The following case is unusual enough to merit publication.

#### CASE HISTORY

A married woman aged 23 was referred to us on May 22, 1947, as a possible case of twins. She had had a normal delivery of a living healthy child on April 7, 1946. Her previous medical history revealed nothing of note. On examination a severe degree of anaemia was present. The abdomen measured 38 in (96 cm). Palpation of the abdomen suggested the presence of twins. X-ray examination next day confirmed the diagnosis and showed that both foetuses were presenting by the breech.

The patient later stated that after the X-ray examination she went home and spent most of the afternoon scrubbing her kitchen floor. She was sick and vomited once during the night. Next day she was uncomfortable all day, complaining of a dragging pain on the right side of the abdomen. She retired to bed at 8 p.m. and slept until about 5.30 a.m., when she was awakened by the onset of labour. The pains were frequent and strong. The midwife did not arrive until about 7 a.m., by which time the first child had been born (at 6.15 a.m.) by the vertex. A neighbour who was present at the time is quite certain about this. The midwife separated the infant and, because of a mass in the vagina, sent for us. By the time we arrived, about 8 a.m., a placenta had been expelled, but the cord led into the uterus. The cord of the already born infant also led into the uterus.

Vaginal examination revealed the second foetus presenting by the vertex in the L.O.P. position. Manual rotation was easily carried out, and two more pains sufficed to expel the infant—dead. The placenta of the living twin was easily expressed some 15 minutes later. At no stage during labour or after did any undue haemorrhage occur, which was fortunate considering the degree of anaemia present.

Both placentae appeared healthy. The opening in the first bag of membranes delivered (that of the second child) was close to the edge. That of the second nearly central. The first child weighed 5½ lb (2.5 kg), the second 6½ lb (3.1 kg). Both were males. The mother made an uninterrupted recovery.

#### COMMENT

The outstanding points in this case seem to be (1) Spontaneous version so near to the onset of labour—less than 43 hours. The events of the day before delivery suggest that version occurred on that day. (2) The unusual sequence of events during labour: foetus A, placenta B, foetus B, placenta A. Such an occurrence must be very rare. We can find no similar case in modern textbooks. Meigs (1856) mentions a case in these words: "I saw a twin labour in which the first child pushed the placenta of its brother before it into the world." He gives no further details and we are left in doubt whether this case was exactly similar to ours. Smellie (Case 411) describes a case in which the membranes of the second child came down in advance of the head and membranes of the first child (McClintock, 1876). Commenting on this, McClintock states that he never met with such an anomaly, and adds "Were it not recorded by such a careful and accurate observer as William Smellie, I would feel inclined to doubt its actual occurrence."

## Reviews

### AMERICAN HOSPITALS

*Hospital Care in the United States* Commission on Hospital Care (Pp 631 \$4 50 or 25s) New York The Commonwealth Fund London Geoffrey Cumberlege (Oxford University Press) 1947

This book is the outcome of an extensive survey, lasting two years of the hospital resources of the United States. It was conducted on behalf of an influential Commission on Hospital Care by a study staff with technical advisers. The Commission was set up by the American Hospitals Association and had the assistance not only of the Public Health Service but of many State administrations and voluntary agencies. While the whole United States is considered, the most complete investigation was carried out in the State of Michigan, and the final recommendations for a co-ordinated system are based upon that territory and the conditions existing there.

The book is described as a study of the function of the general hospital "and is regarded notwithstanding a long list of recommendations as a source book." So it is, and the greater part of its statistical information its tables and charts are applicable only to the USA and of no direct interest to other countries. Indeed it illustrates very well the truism that, interesting and instructive as visits to the hospitals of other lands may be the traveller returns to find his own problem still his own and not to be solved by the experience or the practice of others.

To anyone versed in the survey of British hospitals and familiar with the drastic scheme of reorganization proposed, it will quickly appear that between the lines of carefully worded criticisms and recommendations there is to be read a reluctant recognition that only a national plan nationally financed, will really meet the case. It is stated in so many words that the fundamental financial plan is to enable the patient to buy the service he needs and recognized that the very best service ought to be available to every citizen. To that end voluntary insurance—the Blue Cross Plan—is strongly advocated, and nearly twenty-three million enrolled people pay their hospital bills through its agency. But those bills do not apparently include the doctors' fees and recent visitors to America hear on all sides the complaint that costs and fees have reached a pitch that is beyond the competence even of the insured. Strong as is the feeling in the United States against anything like socialized medicine (by which is meant a national health service such as our own) there is an undercurrent of uneasiness which one can trace too in this book lest the force of circumstances should impose something of the kind.

The survey resulted in some 180 recommendations for the integration and more adequate care of the American public, a study of the function of the general hospital is promised but is borne out only to the extent of present function and does not include examination of fundamentals. There is no satisfying answer to the questions: What should be the function of a hospital in a modern community? What is its job? and Who should do the component parts of the job? Yet there are plenty of indications that the time is ripe there as here for a thorough revision of our ideas if for no other reason than that there is here an immense building and rebuilding programme must be carried out in the future—an immediate future for them, a distant one alas for us.

It is worth listing some of the recommendations. The first is that the survey organization should continue in being. Governmental agencies should use voluntary hospitals so far as possible and all types of hospital including sanatoria those for mental disease and those for chronic diseases should be consolidated as one service with common facilities of all kinds the general hospital being the focal point. State county and municipal hospitals should have advisory boards broadly representative of the public. Full authority and responsibility for administration should be vested in a single administrator but there should be liaison arrangements with the medical staff. The administrator should be responsible for all phases of the nursing programme but the nurses should have ready access

to all levels of authority in the department. Emphasis in a school of nursing should be on the educational aspects, and to that end should be operated by colleges or large hospitals. Non-professional nursing staff should be employed to supplement the work of the professional nurses. Authority should be delegated to the heads of departments. Staff conferences at which attendance is required should be held regularly, their agenda to include 'a careful audit of the medical work in the institution. "Sabbatical leaves" should be open to doctors and nurses of smaller hospitals for further study and experience. Training programmes should be arranged for service staff. Communicable disease should be provided for in general hospitals, which should also undertake the diagnosis and treatment of mental disorders not requiring long-term institutional care. There should be an organized service of convalescence, with dietetic and therapeutic facilities for those returning home but still needing out-patient service. Social service should be financed through regular budget sources. Hospital diagnostic facilities should be at the disposal of the local medical profession, a recommendation which has here been found impracticable however sound in theory. There should be rentable consulting rooms for doctors on the hospital premises. Group medical practice should be promoted. Rehabilitation services should be correlated with community centres. Hospitals and health departments should integrate their functions with joint use of facilities. Public health officers should rank as members of the hospital staff and the department should be housed in or with the hospital. Special inducements should be offered to attract doctors and nurses to rural practice. On finance, 'the maintenance of hospital service should be a direct responsibility of the residents of the area who use the facilities, but there is a saving clause 'in so far as possible' and "general tax funds should be used to purchase hospital care for the indigent. From the same source should come subsidies for research.

The proposed plan for the State of Michigan is not unlike our own. There are two teaching hospitals at the head, with regional centres, community centres and community health centres in rural parts with no hospital. There is far more in the book than is mentioned here. It should be in the hands of all those in this country so busily engaged in similar preoccupations.

E. ROCK CARLING

### RADON

*Radon Its Technique and Use* By W. A. Jennings B.Sc. A.Inst.P. and S. Russ C.B.E. D.Sc. F.Inst.P. (Pp 222, 49 figures 14 plates 18s) London John Murray

In recent years there have been such remarkable developments in atomic physics that a new light has been shed on the whole of man's scientific endeavour, and for those who have been concerned with the use of radiation in medicine it has illuminated paths along which they have hitherto groped their way. The knowledge accumulated through practical experience of medical needs in treating cancer is and will be for a long time the sound basis of radiotherapy. Radon has played a large part in the past, and in experimental technique especially, both clinical and laboratory, it still has important uses for the future. Now that there is a shortage of beds even if radium is preferable to radon for routine clinical work the use of radon offers a chance not to be lightly relinquished of early treatment of some cases. A book on radon is therefore of practical interest to all who are concerned with radiotherapy. This particular book, written by specialists in the production and use of radium and based as it is on many years' experience in improving and adding to the technical and scientific knowledge of radon should appeal to a wide public of scientists because of the wealth of information it contains and because it is a lively example of the diversity of interest that may result from the sincere and painstaking exploration of a relatively narrow field for practical purposes.

Everything one may wish to know about radon is to be found within its pages, including its source, physical and chemical properties, extraction, purification, measurement and uses. There is much discussion of its clinical use and the authors consider the dosage systems and methods which may be used to determine the distribution and content of radon sources to achieve a known uniform dose. Clear line diagrams and excellent photographs contribute to the easy understanding of a

lucidly written text, which is impressively up to date in referring to pertinent work in the same field

The authors suggest a layout for a national radon centre. It is to be hoped that the work may be continued in such a centre and that radon will continue to be available so that the tradition of hard and careful work which lies behind this book can continue. The technicians who have helped to build this tradition may rightly consider that the authors have produced a worthy memorial to their skill and devotion.

FRANK ELLIS

## OCULAR MUSCLES

*Neurology of the Ocular Muscles* By David G. Cogan, M.D. (Pp 214, 121 illustrations, \$6.00 or 25s.) Springfield, Illinois: Charles C. Thomas, Oxford: Blackwell Scientific Publications.

*The Oculomotor Muscles* By Richard G. Scobee, B.A., M.D. (Pp 359, 112 figures, 40s.) London: Henry Kimpton, 1948.

The little book by Dr Cogan, the Associate Professor of Ophthalmology at Harvard and Director of the Howe Laboratory of Ophthalmology at Boston, although restricted in scope, is good. The author discusses the neurology of the extraocular muscles and the pupil, their nerve pathways and intramuscular connexions, from the point of view of the neuro-anatomist. The subject is difficult and confused, on the borderline between ophthalmology and neurology, and the author has done a considerable service in collecting much information which may not readily be available to those concerned primarily with either specialty. He emphasizes throughout the topographical analysis of the lesions which cause the multitude of signs and symptoms associated with the ocular motor system rather than the aetiology of the lesions themselves or their treatment. To a large extent this is rational, for the clinical evidences of disease in this region are determined by its site rather than its nature, and in clinical practice the primary concern of the neuro-ophthalmologist is with location. The unravelling of the clues presented in cases of this type may be one of the most difficult and perplexing tasks the ophthalmologist or the neurologist has to face and a topographical approach is the only one which offers an easy solution. With these reservations the book is very complete and up to date, it is fully and instructively illustrated, and not the least of its virtues is the exhaustive list of references.

The book by Dr Scobee has evolved from the writer's lectures to graduate students at the Washington University School of Medicine and covers the whole field of ocular motility. He briefly describes the anatomy, physiology, and neurology of the extraocular muscles, then follows sections on heterophoria and squint—surprisingly, nystagmus is not mentioned. In a large section he discusses the clinical methods of diagnosis, and the final chapter is on treatment in which non-operative methods receive little attention, orthoptic techniques are brushed aside even in cases of insufficiency of convergence, and attention is given almost entirely to surgery. In surgery the author is an enthusiastic follower of Chavasse in advocating the value of weakening the antagonist of a paretic muscle rather than strengthening the muscle itself—a thoroughly sound orthopaedic principle which, however, has its limitations.

STEWART DUKE-ELDER

The vastness of current literature makes it difficult for an individual to keep pace with the advances in medicine. The 1947 *Year Book of General Medicine* edited by Dr G. F. Dick and others (H. K. Lewis, 21s.), is especially welcome not as a substitute for the reading of original papers, but as a guide to observations of clinical interest made during the past year. It covers the fields of infectious diseases of the chest, haemopoietic system, kidney, heart and blood vessels and gastro-intestinal tract. It is impossible to comment on all the articles of note but, choosing at random, we have for example an account of the accumulated experience of American workers with streptomycin, not only in tuberculosis but in various other infections for which the drug is now available in Britain. The advent of folic acid has given a great stimulus to research in the field of megaloblastic anaemias and there are several papers in the *Year Book* on the complicated relationship of pteroylglutamic acid to these anaemias. Such interesting rarities as a severe necrotizing form of pyelonephritis in diabetes are also discussed. The papers are in general well selected and the book is up to the standard of its predecessors. The editorial comments add greatly to the value of the summarized articles.

## BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

*Reid's Practical Sanitation* By J. J. Buchan, M.D., D.P.H. 24th ed. (Pp 300, 18s.) London: Charles Griffin, 1948.

Intended particularly for students who propose to become sanitary inspectors.

*Voluntary Medical Care Insurance in the United States* By F. Goldmann, M.D. (Pp 228, 16s.) London: Geoffrey Cumberlege, 1948.

An analysis of the present situation and an account of its development.

*Motivation in Health Education* The 1947 Health Education Conference of the New York Academy of Medicine. (Pp 53, 5s. 6d.) London: Geoffrey Cumberlege, 1948.

The theme is how the educator can best make his teaching effective in the conduct of his pupils.

*The Leptospiroses* By P. H. van Thiel. (Pp 231, 16.50 francs.) Leiden: Universitaire Pers Leiden, 1948.

A monograph on the morphology of the leptospirae, with an account of the diseases caused by them.

*Aids to Anaesthesia* By V. Goldman, L.R.C.P., M.R.C.S., D.A. 2nd ed. (Pp 316, 7s. 6d.) London: Baillière, Tindall and Cox, 1948.

A summary for students and house officers.

*A Handbook of Parentcraft* By L. G. Housden, O.B.E., M.D. (Pp 152, 5s.) London: Eyre and Spottiswoode, 1948.

A practical handbook for women.

*Practical Section Cutting and Staining* By E. C. Clayden, F.I.M.L.T. (Pp 129, 9s.) London: J. and A. Churchill, 1948.

An introductory book for laboratory technicians.

*Advances in Pediatrics* Edited by S. Z. Levine et al. Vol. 3. (Pp 363, 45s.) London: Interscience Publishers, 1948.

Eight monographs on physical and mental disorders of children.

*Men of Stress* By Harley Williams. (Pp 374, 15s.) London: Jonathan Cape, 1948.

Biographies of Woodrow Wilson, Andrew Carnegie, and Lord Leverhulme.

*Elective Alimentary Rest and the Elimination of So Called "Paralytic Ileus" After Abdominal Operations* By V. J. Kinsella, M.B., Ch.M., F.R.C.S., F.R.A.C.S. (Pp 35, 3s.) Sydney: Angus and Robertson, 1948.

Reprints of three articles on post-operative treatment.

*At Home with Income Tax* By R. W. Harris. (Pp 191, 8s. 6d.) London: Stone and Cox, 1948.

An exposition of income tax in simple terms.

*Medical Writing* By M. Fishbein, M.D. 2nd ed. (Pp 292, No price.) Philadelphia: Blakiston, 1948.

A manual to help the medical man express his thoughts clearly in English.

## H 11 IN MALIGNANT DISEASE

The report of an inquiry by a committee of the Medical Research Council into the effect of H 11 in the treatment of malignant disease is published in the opening pages of this issue. H 11 is an extract of male urine which is claimed to have an inhibiting effect on malignant disease in man. The idea that growth-controlling agents may be present in the tissues, serum, or urine is not new. At various times extracts of connective tissue, placenta, gonads, thymus, spleen, and other tissues have been used in the treatment of cancer. All have much the same effect. There is a transient diminution of pain, improvement in appetite and sense of well-being, and in many cases a diminution of the size of the tumour, often with softening at the margin or throughout. Very rapidly, however, the malignant process resumes its downhill course. For this reason such treatments have rarely spread beyond their enthusiastic originators.

The Medical Research Council committee comes to the conclusion that there is no evidence of inhibition of malignant disease by H 11 in man or animals. It must be noted that the claims made for H 11 in human cancer are hedged by certain restrictions. Cases are not included for analysis unless they survive for at least two months after beginning treatment with H 11. The criterion of success is arrest or regression of the primary growth, and no claim is made for prolongation of life, though there is inevitably an implication to this effect. There are no figures in the literature for the natural history of patients with cancer who are well enough to survive two months and who will usually have had treatment by operation, radium, x rays, or other measures. Most surgeons of experience would conclude that many such patients would live for long periods, and some of them would have apparent remissions. The data on the effects of H 11 are collected by postal follow-up, in most cases from general practitioners. Few general practitioners will see more than three or four cases of cancer a year, and the measurement of tumours is an extremely difficult operation. In records of any new treatment of cancer the statistician expects that at least 90 to 95% of patients will be followed up. How very different the position is with H 11 is shown by the following quotation from a paper<sup>1</sup> from the Hosa Laboratories:

A total of 3 885 patients had received injections of H 11. Extract. Of these 1,551 had received treatment for less than two months and were therefore not considered adequately treated for any analysis and 963 had been treated for over two months but were insufficiently documented for analysis. Of this latter group of 963, 571 cases were outside the United Kingdom in itself an adequate explanation for the lack of data. There remain 1,371 cases who have been treated for an adequate

length of time to be of significance and whose details are sufficiently known for analysis.

It is not surprising that the only conclusion the committee could draw from the Hosa records was that there was no evidence that H 11 had any effect on cancer and that the records themselves were worthless as material for clinical research. The acid test of any remedy for cancer is increased duration of survival, but the methods of distributing and reporting on H 11 are such that no information about this crucial point can be obtained. It may well be asked why better-controlled trials of H 11 have not been performed. No clinical trial will carry conviction unless a series of cases is observed throughout the course of treatment by a cancer specialist or group of specialists and compared with similar patients not treated with H 11. The reason no such trial has been made is that the conditions imposed by Mr Thompson, the discoverer of H 11, have appeared to investigators to restrict their freedom of action and judgment and have not been acceptable. Some of the difficulties in satisfying Mr Thompson can be seen from the account of Dr Bonser's animal experiments, which seem to the unbiased reader to show an entire absence of scientific foundation for the therapeutic use of H 11.

It is unfortunate that a group of sincere laymen who are interested in H 11 have apparently come to the conclusion that there is a conspiracy on the part of organized medicine, and particularly the *British Medical Journal* and the Medical Research Council to suppress a discovery which is of enormous benefit to mankind. It is difficult to see any grounds for this belief, or for the attacks made on the good faith and scientific competence of investigators like Dr Gye who have given up time and facilities to testing H 11 and have obtained negative results. Details about H 11 have been published in papers in *Nature*<sup>2</sup> and in other journals. It has been available to the whole world for confirmation, but no confirmation has arrived. No, it is not convincing to cast Mr Thompson in the role of Semmelweis or a Freud, as a pioneer who is misunderstood by his generation. There is already a vast literature on the chemotherapy of cancer. There has been no hesitation in the use of oestrogens in prostatic cancer, nitrogen mustard in Hodgkin's disease, or urethane in leukaemia. Incurable cancer is a painful condition to the attendant as well as to the patient, and no remedy which offers any chance of effect is likely to be left untried. The cost of treatment with H 11, including the associated biochemical tests, is high, but that would be no bar to its employment if it were effective. The plain fact is that H 11 has been tried and found wanting, and whatever justification there may be for further experimental work on it there is little or none for continuing to distribute it to patients.

## WORK AND THE MAN

In our present industrial predicament, when the greatest possible output per man hour is demanded, continuous efforts to fit man and job together are obviously necessary and important. As is so often the case, study of experience in the U.S.A. is well repaid, provided that judgment is carefully reserved on whether the methods used and the conclusions reached there are relevant to our problems.

<sup>1</sup> Olfertshaw G J W. and Lowe E. *Cronin Medical World* 1946 65 231.  
<sup>2</sup> Thompson J H. Holt P F. and Jones R. *Forbes Nature* 1943 151 24.

here On the west coast of the Atlantic the problem is posed as "What affects capacity and fitness for work?" On the east coast, however, the question is put somewhat differently "What is occupational or industrial health and how is it modified?"

In discussing the respiratory and circulatory capacity for work Dill<sup>1</sup> points out that the heaviest known lumbering work requires only about a third of the greatest possible respiratory effort of which a man is capable, although naturally the effort has to be sustained for many hours a day and not merely for a few minutes. He thus raises the question of the relevance of the short "all out" respiratory test to the less intense but more sustained effort needed in the highly complicated situation which is found in most industrial jobs. Moreover, he points out that it is highly artificial to separate the circulatory from the respiratory capacity, since both are clearly parts of a combined operation for the transport of the factors necessary for the functioning of the cell. Perhaps, therefore, the best commentary on Dill's experience is the common observation many of us made as schoolboys that the boy who wins the hundred yards is never the boy who wins the three miles.

The importance of adequate nutrition is stressed by Keys,<sup>2</sup> who questions the existence of so-called "sub-clinical" deficiencies and the efficacy of multiple vitamin supplements. Few, however, will be so dogmatic as to doubt that there is some falling off in health between the onset of deprivation and its obvious appearance as a clinical deficiency. May not the effect first be shown, for example, in an increased incidence of disease or by some falling off in performance at the job? In England the late war taught the receptive industrial dietitian much about such things as the regularity of meal timing and the importance of variety in the menu. Night work demanded (and may demand again) a different kind of food as well as different hours of eating, and sentiment and habit were found to be almost as important as science in the right design of diet.

Disease reduces the capacity for work, and in America, as in England, the emphasis of interest is on the extent of the reduction which occurs in the industrial pneumoconioses and in heart disease—which is mainly of social (i.e., rheumatic) origin. Whether welder's siderosis causes incapacity is still an open question, and in silicosis it seems to be the complications of emphysema or infection, usually with tuberculosis, which produce the disability rather than the original disease. Evidence on both sides of the Atlantic suggests that the extent and nature of the radiological opacities in this disease bear little or no relation to the disability of the patient in relation to his job.

In no branch of medicine are clinical courage and steadiness of decision more called for than in cardiology, and the real dangers are not that the patient may suddenly drop down dead from doing too much work but that he may have his capacity for work injudiciously lowered by his physician and become thoroughly frightened about his condition even to the extent of developing a cardiac neurosis. Once acquired this is not easily cured. In Czechoslovakia during the war patriotic doctors certified

that large numbers of their countrymen were suffering from heart disease in order to prevent their employment by the Germans. When the war was over, however, many of these patients were found to have cardiovascular neuroses which could not easily be thrown off. Full employment within the real cardiac reserve irrespective of the noises made by the heart, careful supervision of the recovered rheumatic case to detect subsequent attacks, and suitable self-control by the physician in the diagnosis of cardiac disease seem to summarize the experience both here and in America.

In a discussion of the factors essential for fitness Fishbein<sup>3</sup> stresses the overriding importance of the common-sense psychology of the total situation. The significance of this is being more and more appreciated here, having been underlined by Bashford<sup>4</sup> and more recently by both the new Nuffield Professors of Industrial Health at the 1947 meeting of the British Association in Dundee. No one can quarrel with Fishbein's recommendation that personal hygiene and dietetics should be included in the educational curriculum and that accident and disease prevention should receive more attention in industry. However, his suggestion that a programme of physical fitness must start by deciding first of all who shall marry and who shall conceive is good logic but poor politics, and would probably be received here with either cold hostility or incendiary language, according to taste.

The figures showing why some 6,700,000 young Americans were rejected for military service in the late war are quoted by Eanes<sup>5</sup> to support the need for a campaign for fitness in the USA. But it is surely important to realize that fitness is a relative term and that it is necessary to ask not only what fitness is but also what it is for. Thus we read that only 9.5% of whites but as many as 32.6% of negroes "failed to meet the minimum standards of intelligence," which was the second commonest cause for rejection. This both prompts the reflection that there are many jobs in the Services which do not need much intelligence, and also poses the questions, How was the "intelligence" tested? and, Was the tester a white man or a negro? In addition there was said to be a considerable proportion of illiteracy among the otherwise mentally normal, but even here there are pitfalls, as was recently demonstrated at a meeting when an expert on this subject was asked his definition of illiteracy. He replied that it was inability to spell monosyllabic English words at a given age, and after a short pause one of his audience remarked, "Such as phlegm!" In England, with our much smaller population in relation to the job to be done, such "above or below the line" methods have little place, and what is needed is a flexible assessment of both man and task with subsequent fitting of the two together. The late war demonstrated a fact which is confirmed by everyday civilian experience that, given enough determination, grave physical disability does not necessarily stand in the way of a good day's work, and the USA itself has provided an outstanding example of this in the personality of the late President Franklin Roosevelt.

The general conclusion, then, both from American experiences and from our own, seems to be that capacity

<sup>1</sup> *Occup Med* 19-6 2, 531    <sup>2</sup> *Ibid.* 19-6 2, 536    <sup>3</sup> *Ibid.* 19-6 2, 566  
<sup>4</sup> *Brit J Ind Med* 19-4 1, 7    <sup>5</sup> *Occup Med* 19-6 2, 572

or work can best be measured by trying a man on a real job, or on as close a copy of it as can be arranged, and then by expressing the result numerically. No simple test of a single system is likely to be successful, and the relevance of a short "all out" effort to a whole day's work needs further consideration. Moreover, the question of incentives must not be ignored, especially in the armed Forces or in geographical areas where the industrial morale is low.

Fitness for work means nearly the same as health, it is a term relative to the task to be attempted, and differs not only between individuals but in the same individual at different times. Its definition and measurement are both at present two of the growing points of medicine. Moreover, the maintenance of fitness depends at one end of the scale upon such elemental necessities as food and houses, and at the other upon the successful prosecution of research by our new departments of social medicine and industrial health. These and many other problems of industrial medicine were discussed at the Ninth International Congress of Industrial Medicine held in London last month.

### VITAMIN-A DEFICIENCY

Since it began work ten years ago the Ministry of Food has always been aware of the risk of vitamin-A deficiency in this country. As a safeguard the addition of vitamin A to margarine was made compulsory, this was possible mainly because of the large amounts of this vitamin in the livers of antarctic whales. The public has also been exhorted from time to time to eat more carrots and green vegetables for the sake of the pigment carotene, which is converted to the vitamin in the animal organism. It thus comes as an unpleasant surprise that Dr John Yudkin and Miss Stella Doraiswami, in an article appearing elsewhere in this issue, should report that about one-fifth of the women university students whom they examined appeared to be suffering from vitamin-A deficiency. They used two independent methods of investigation, both of which gave similar results. The efficiency of dark-adaptation was measured before and after dosing with vitamin A, and students whose powers of adaptation improved significantly on the second occasion were assumed to have been deficient in the vitamin. Investigation by the usual method of dietary survey showed defective intakes in about the same proportion of students as were found defective by the dark-adaptation test. Unfortunately only a few could be examined by both methods, but the limited evidence indicated that the administration of the vitamin improved dark-adaptation only in those with the lowest intakes of vitamin A and carotene.

Many investigations have been concerned with the clinical importance of degrees of vitamin-A deficiency. In 1937 Moore<sup>1</sup> described a survey in which the liver reserves of persons accidentally killed were estimated by a chemical method. A median reserve of 220 i.u. of vitamin A per gramme was found, which was calculated to be sufficient to allow survival on a diet deficient in vitamin A for several months. This conclusion was later fully confirmed in experiments conducted during the war at Sheffield by the vitamin A Subcommittee of the Medical Research Council,<sup>2</sup> when members of a group of volunteers all subsisted for at least a year on a deficient diet without signs of depletion. Moore's investigation, however, had shown a wide variation in the vitamin-A reserves of individuals, with extreme values of 10 and 1,500 i.u. per gramme. The possession

of adequate reserves by the majority of the population, therefore, was no evidence against a significant degree of deficiency in a minority. Harris and his colleagues,<sup>3</sup> using the dark-adaptation method, found support for this: there was evidence of deficiency in about 36% of elementary school-children in the poorer quarters of London. On the other hand, signs of deficiency were found in only 5% of adult men examined at Cambridge, presumably they were better nourished. In 1944 Yudkin and his colleagues<sup>4</sup> observed that the administration of vitamin A to school-children was without effect, but there was some statistical evidence that the nutrition of factory workers was improved.

While we may expect wide variations in the consumption of vitamin A by different groups of people, and by the same groups at different times, care is needed in interpreting results obtained by the dark-adaptation test. Good vision in the dark presumably depends *inter alia* upon the ability of the blood to keep the retina supplied with vitamin A. The actual amount of vitamin present in the retina, however, is only a minute fraction of that in the blood stream, which in normal circumstances is again less than 1% of the main store in the liver. Between the intestines, liver, blood plasma, and non-hepatic tissues such as the retina a sensitively balanced system of absorption, storage, mobilization, and distribution must operate. It is therefore possible that giving large doses of vitamin A may improve dark-adaptation by temporarily increasing the amount in the blood rather than by making good a real deficiency. Doraiswami and Yudkin, however, made allowance for the temporary rise in the level of vitamin A in the plasma by testing for dark-adaptation 24 hours after the vitamin had been given. Their conclusion that a proportion of students were really deficient in vitamin A therefore seems justified. It is doubtful, however, whether we should infer from these observations that there is not enough vitamin A and carotene in the national dietary. Other students, living under similar conditions, succeeded in getting far more than they required, while the Scottish students examined by Dr R. P. Cook, whose paper appears on page 711 of this issue, seem to have had no difficulty in attaining satisfactory intakes. It would be logical to ask, therefore, whether the vitamin-A-deficient students had poor appetites for all foods or a special dislike of vegetables or fats. But all the same, if faulty eating habits can be so prevalent in a well-managed women's college where the teaching of nutrition is part of the curriculum, it would be unwise to be complacent about the vitamin-A intake of other groups.

### MINORITY REPORT ON NURSES

Minority reports are usually limited to a few disapproving paragraphs, but Dr John Cohen,<sup>1</sup> of Leeds University, in his dissent from the report of the Working Party on the Recruitment and Training of Nurses extends himself to two-thirds of the length of that document. He was unable to sign the report with his colleagues because he believed that, in the first place, their recommendations failed to take sufficient account of the relation between the planning of nursing and other health services and between all such planning and that of the country's manpower resources as a whole. He thought also that the extent to which the methods of psychological research can provide information for determining nursing and medical staff ratios or the length of training periods for nurses was inadequately appreciated by the majority. At present, in Dr Cohen's view we are as ill equipped to plan a nursing service as we

<sup>2</sup> British Medical Journal, 1947, 2, 422, 426.

<sup>1</sup> Blackett J. 1937, 31, 155.

<sup>2</sup> Nature, 1945, 156, 11.

<sup>3</sup> Lancet, 1937, 2, 1009, and *ibid.* 1939, 2, 1299 and 1355.

<sup>4</sup> Publ. Hlth. Lond. 1944, 57, 109, and Brit. J. Ophthalm. 1944, 28, 556.

architect would be in planning a house without knowing the size of the projected dwelling, the labour and materials required, or the number of tenants. No solution, he says, can be found without a radical change of attitude towards research in the social sciences. What is wanted is a comprehensively planned health service with a correct determination of the number of hospitals, beds, and doctors required, and such a plan in turn presupposes a planned national economy in which the correct proportion of our national resources is devoted to health.

The majority report<sup>2</sup> spoke of an outworn disciplinary system in hospitals, and here Dr Cohen dots the "i's" and crosses the "t's". He believes that the disciplinary system, associated with unsympathetic handling of pupil and junior nurses by ward sisters and other senior nursing staff, is probably the main cause of student wastage. He says that the average hospital so far as its nurses are concerned tends to be a self-contained, segregated community of women, functioning through a more or less rigid hierarchy of staff, sometimes of a quasi-military character. It tends to perpetuate ways of life which in the outer world are obsolescent. Hospitals are run as authoritarian, not as democratic, institutions. The situation might be improved by bringing into the hospital the equivalent of the joint production councils which have proved useful in industry.

Two other suggestions in Dr Cohen's report may be mentioned. One is that more attention should be given to the amount and quality of nurses' food. It may well be true that in an institutional environment where the range of interests and activities is severely limited diet assumes a special significance. The other is that the nurse's remuneration should be assessed on the basis of her productivity—the savings, primary and secondary, direct and indirect, which result from her labours. The outcome may be quite surprising. The nurse may prove to be, not only sentimentally but in terms of hard economics, one of the most valuable members of the community.

### ABDOMINAL DISTENSION AND DFP

Di isopropyl fluorophosphonate or DFP, which was prepared in the course of research on chemical warfare, is the most active of the group of substances first shown by Adrian, Feldberg, and Kilby<sup>1</sup> in this country to inhibit the action of cholinesterase. Its properties are very similar to those of phisostigmine. Thus the movements of the gut, now known to be maintained by the liberation of acetylcholine in the wall of the gut, are greatly increased by DFP because it prevents the destruction of acetylcholine. It has been used successfully in the treatment of abdominal distension. Grob, Lilienthal and Harvey<sup>2</sup> first observed that the daily administration of DFP to 60 normal subjects caused abdominal cramps and diarrhoea, and they therefore investigated its action in three volunteers by recording the pressure changes inside a Miller-Abbott balloon lying in the intestine. The intramuscular injection of 2 mg of DFP in 0.1% solution in arachis oil increased the motility of both small and large intestine about one hour after the injection. Rhythmic contractions of greatly increased amplitude occurred every two to three minutes over a period of two to five hours. The increased intestinal motility caused by DFP was inhibited by giving morphine or pethidine or atropine. This observation is important because of the practice of some surgeons in this country of treating paralytic ileus with morphine. The authors also found that when DFP was being given the intestine became more sensitive to the action of pituitary (posterior lobe) extract and to the action of neostigmine ("prostigmin").

This increased sensitivity persisted for one to three weeks after the last dose of DFP.

Harvey and his colleagues then tested the action of DFP on 64 patients with moderate or severe paralytic ileus, 46 of these had distension following major abdominal operations, eight had peritonitis, five had severe pneumonia, and five had lesions of the spinal cord. Enemas and the use of a rectal tube had been ineffective. In the less severe cases relief was obtained after the intramuscular injection of DFP alone. An initial dose of 2 mg was followed by further doses at intervals of eight to twenty-four hours. In some of the more severe cases DFP did not fully relieve the distension, but the additional injection of neostigmine (0.5–1.0 mg) proved effective. Pituitary (posterior lobe) extract was given in addition to neostigmine in a few cases. The authors state that they had no failures in this series. It is to be hoped that DFP will soon be available for use in this country.

### DILATATION OF THE OESOPHAGUS

The underlying cause of cardiospasm has so far eluded discovery. The most favoured hypothesis at present is that the condition has a psychogenic origin, and in a recent review of 47 cases Wooler<sup>1</sup> is inclined to support this opinion. It is difficult to believe that this can be the whole truth, since the condition not uncommonly occurs in children of less than one year of age. It seems probable that the solution lies in the search not for one but for several causes. The association of cardiospasm with congenital megacolon is known, and the high incidence of the disease in Brazil is as remarkable as the frequency of congenital dislocation of the hip in Italy. Both these facts suggest a familial origin for at least some of these cases. Wooler rightly stresses the importance of observing the barium swallow rather than relying on radiographic examination alone, and he describes the return after treatment of the three different types of muscular movement of the oesophagus in the reverse order of their disappearance. Once cardiospasm has become established a mega-oesophagus, which is in fact a "large, tortuous, patulous bag," may eventually develop. This presents a mechanical problem which psychotherapy cannot hope to cure.

So long as it is undecided whether this type of dysphagia is an achalasia, a true spasm, or indeed whether, as suggested by Negus, the trouble lies at the crico-pharyngeal sphincter rather than at the cardia, the treatment must be empirical. Wooler has had good results with the Negus hydrostatic dilator. He treated 38 of his patients by this method, and in 27 relief of symptoms was complete. He has found, however, that young children do not respond as satisfactorily as adults. When the mechanism of this cardiac "sphincter" and its relation to the diaphragmatic "pinchcock" have been decided the problems of cardiospasm and of peptic ulceration of the oesophagus will be further elucidated, and the place of sympathectomy, oesophago-gastrostomy, and Heller's operation (longitudinal incision of all the muscle fibres down to the mucosa) will be more definite. For the present the treatment of choice is the use of the hydrostatic bag for dilatation of the sphincter, the other methods being held in reserve for those cases in which it fails.

The cardia is one of the great meeting-grounds of the surgeons. The thoracic surgeon gets the best view of it from above, it is rather less accessible for the abdominal surgeon, and even less so for the otolaryngologist. Each approaches the problem of cardiospasm from a different standpoint, both intellectually and physically. The pooling of their respective views should continue.

## FUNCTIONING TUMOURS OF THE OVARY

ADDRESS BY DR EMIL NOVAK

The Royal College of Obstetricians and Gynaecologists has instituted an Anglo American Lecture designed to cement more closely the bonds of friendship between Great Britain and the United States. The first lecture was delivered on Oct 1 by Dr EMIL NOVAK of Johns Hopkins University President of the American Gynecological Society. The interest in the lecture, over which Sir William Gilliatt presided, was so great that the meeting room at the Royal College proved insufficient to accommodate those attending, and an adjournment was made to the Barnes Hall of the Royal Society of Medicine, which was crowded out.

Dr NOVAK said that his main interests were clinical, but his scientific recreation had always been in the fields of pathology and endocrinology and this had led him to the study of certain functioning tumours of the ovary. These tumours were relatively rare but clinically important, and the signs and symptoms included sex disturbances of an unusual character. In his laboratory he had material from about 160 cases only a fraction of which had come from his own clinic. No clinic could expect to have any large number of these tumours, his own collection had been assisted by the ovarian tumour registry of the American Gynecological Society—a registry which had been in existence for four years.

There was nothing new in the concept that tumours might retain functioning capacity. That was true of a cancer of the liver, which in some cases maintained the capacity to secrete bile, certain tumours of the intestine could still produce mucin. But this characteristic pertained particularly to the endocrine group of tumours, of which many examples could be given, such as the calcium and phosphorus metabolism of hyperparathyroid tumours and the remarkable sex changes seen in association with certain tumours of the adrenals. The ovary being included in the endocrine mechanism, might also contain tumours which functioned. Meyer, from a careful study of his material and a critical analysis of much that had been reported previously, gave a good classification and a fair working theory of the nature and histogenesis of these tumours. Perhaps this was now somewhat inadequate, but his groupings had been useful during the last sixteen years.

A common characteristic of these tumours was that they were made up of cells relating to an early embryonic phase of ovarian development. At a very early stage in the embryonic history of the ovary there appeared on the posterior surface of the abdominal cavity a structure on which was formed the so called genital ridge. Here a collection of cells indicated the future location of the gonad, either ovary or testis, and a point to be stressed was that in the early stage no one could tell which it was going to be. Therefore embryologists spoke of an early undifferentiated stage of gonadal development. In this stage certain collections of cells might be detached and remain dormant for years while differentiation went on above them.

From these undifferentiated cells tumours might arise later in life. These separated tumours had been given by Meyer the name of dysgerminomas. If the theory was correct, tumours of this group should also be observed in the cells of the testis, and this was certainly the case. It was impossible to distinguish histologically a dysgerminoma of the ovary from a seminoma of the testis. When these dysgerminomas were first described it happened that many were found in individuals who presented some degree of sex abnormality, a number were found in pseudohermaphrodites and others in women with moderate degrees of homosexuality. It was at first thought that this was a characteristic association, but since then a great majority of the cases had been found in normal women. There might be minor degrees of abnormality—small ovaries or long periods of amenorrhoea—but even if the dysgerminoma were seen in a pseudohermaphrodite it had nothing to do with that condition and if the tumour were removed the pseudohermaphroditism would remain as before.

### Beginnings of Sex Differentiation

In the development of the ovary the undifferentiated phase was succeeded by evidences of differentiation. Evidence was accumulating in favour of differentiation *in situ* and not by

invagination from the surface epithelium. In the gonad which was destined to become a testis zigzag cords of cells formed which later became canals, and the testicular structure went on to completion. In the case of the ovary exactly the same scaffolding was laid, the ovary first passing through a sort of testicular phase. It appeared, said Dr NOVAK, that woman as the superior being, was built upon the vestigial remains of the male structure. This primitive scaffolding was first laid down, and then a second phase of differentiation began, again *in situ*. Vestiges of the first testicular structure persisted in the ovary, and the tumours came from cells of the proto testicular type which were latent in every woman. The tumours to which these gave rise were the arrhenoblastomas.

In further development of female differentiation, with the formation of large accumulations of cells, evidence was seen of a peculiar architecture. Around each potential ovum there appeared a group of satellite cells—the first suggestion of the primitive follicle of the ovary. According to the original concept of Meyer, which had now to be extended, these were redundant granulomatous structures from which grew granulosa cell tumours. But this theory did not explain closely allied cells which were made up of connective tissue, and from these cells also connective tissue or epithelial tumours might arise. The glands were definitely of the feminine gender and produced sex hormones. Thus there were arrhenoblastomas which were thought to arise from vestiges in the ovary and of which no one could give a stereotyped description, for the term covered a wide range of tumours, and there were tumours which presented a resemblance to adrenal tissue and were spoken of by some authorities as lutein cell tumours. It was necessary to bear in mind in considering the histogenesis of these tumours the great differentiation potency of the ovarian tissues, which even without the spermatozoa by some unknown mechanism could occasionally produce some resemblance to a foetus or parts of organs or tissues.

### Problems of Treatment

In treating these tumours the important issue was between conservative and radical procedures. When the tumour was inclined to burst the capsule treatment should be radical, but in the young woman, if the capsule was unbroken, the treatment should be conservative and the outlook was relatively good. The lecturer mentioned one case in a child aged 7 who had a huge tumour filling the abdominal cavity. On section it was found to be a dysgerminoma. Under radiation it faded away, returned and was again treated, but there always remained the irreducible nodule which grew continually and caused death after a few years. Such cases always ended fatally.

Another case of which he gave the clinical history was a woman aged 32 who had had one child and had menstruated quite regularly until 13 months before he saw her. Her voice was then deep, raw, and husky, and she had a fine growth of hair on face, chest, and extremities. She proved to have a unilateral adrenal tumour about the size of a golf ball. That sort of history, plus a unilateral tumour, in a woman who had had a normal feminine make up should always make one think of a masculinizing tumour, but a mistake was often made when a unilateral tumour was found in a woman who had always had certain masculine characteristics. In such cases the tumour was often taken to be of the masculinizing type, whereas generally it was of some simple everyday type. If, on the other hand, a woman had had a feminine history and then passed through a masculinizing phase, the significance was far greater. The first of the symptoms was usually amenorrhoea, this was not a masculinizing symptom, but it was a defeminizing one and the same was true of regression of the breasts and loss of subcutaneous tissue around the hips. These changes were likely to be followed by positive stigmata—growth of hair on upper lip, chin, cheeks, forearms, and chest. Hirsutism again was not in itself evidence of masculinization, every gynaecologist had seen women who had had a succession of children and yet were covered with hair. But it might be a part of masculinity and, associated with a deepening voice, must be regarded as something positive. With the removal of the tumour these symptoms disappeared, menstruation returned, almost within a month, and the figure became fuller, but the regression of the positive symptoms—hirsutism and the deep voice—might be much slower. These tumours were much less malignant than

the ordinary ovarian tumour, but he thought nevertheless that many gynaecologists took them too lightly. There was a great risk of recurrence, which he put at 25%, and recurrences ultimately proved fatal.

Speaking of feminizing tumours of the ovary, Dr Novak said that the physiological characteristic was the production of oestrogen, and in a woman no outstanding changes might be expected, though menstruation might be excessive and irregular. On the other hand, if the oestrogen was released in childhood long before the time of normal production very striking effects were seen in the way of premature puberty. In young children a tumour was usually thought of, but if it could not be palpated it was unwise to assume that it was present. It was better to watch the case, and if no tumour developed the child must be considered normal, except for precocious puberty, entailing long periods of embarrassment which called for psychological treatment. A girl with a granulosa cell tumour could not conceive. In appearance the substance of such tumours was greyish, sometimes yellow, and there was a tendency to cavity formation. The microscopical diagnosis was not difficult, it was based on two considerations—the morphological resemblance of the constituent cells to granulosa cells and the typically granular architecture. One new line of research in connexion with granulosa-cell tumours was suggested by the fact that if ovarian tissue were implanted in the spleen of a castrated animal a granulosa-cell tumour or lutein-cell tumour would develop in the implanted area.

### Medicine as a Planned Economy

SIR—Among lay people and even among doctors there is a widespread impression that the scientific quality of medical practice is in some way dependent on the part played by the laboratory. There is a failure to appreciate that science is an intellectual method and does not reside in an instrument or manifest itself in a technique. Dr Frangeon Roberts (March 13, p 487) and Dr E B Hendry (Sept 18 p 567) have pointed out that as a result of this erroneous belief radiologists and bacteriologists find themselves overwhelmed with unnecessary demands for their services.

New methods of investigation are trusted too highly and in their haste to use them physicians tend to dispense with older but well tried clinical methods. It takes time and patience to take a careful history, observe the patient, and think about the diagnosis, and these methods have no novelty, do not appeal to a superficial desire to be scientific, and are too likely to be treated by the patient and doctor as troublesome preliminaries to the reports from laboratories on which the diagnosis will eventually be made. Dr E B Hendry has reported that an unenlightened attitude to biochemical investigations has resulted in countless demands for unnecessary tests which seriously hinder more valuable work in the laboratory. As the number and complexity of modern techniques of investigation increase other specialists will free the difficulties which to-day harass biochemists and radiologists. Although many solutions are proposed for this difficult problem none is alone of value.

*Mechanization*—There are a small number of really valuable tests which are frequently called for, and it is surely not beyond human ingenuity to devise semi-automatic methods so that such tests can be done accurately and rapidly in large numbers by unskilled workers. The estimation of the haemoglobin content of blood, the detection of tubercle bacilli in sputum, and blood urea estimation would be such tests which would require urgent consideration.

*The Valuation of Tests*—Workers in laboratories and x-ray departments have contributed to their own discomfort, and deserve criticism for failing to impress upon their colleagues the limits of accuracy of many of their present techniques. Haematologists know that an ordinary red blood-cell count has wide limits of accuracy, but they have failed to make this widely appreciated if they had their technicians would be asked to do less interminable red cell counting. In radiology it is too frequently assumed that an accuracy of diagnosis is obtained which can only be reached by the most skilful, the most painstaking, and the most time-consuming radiological technique. Radiology is not aiding clinicians if it continues to allow them to accept such a high valuation of radiological diagnosis that clinical examination and history are either neglected or their evidence relegated as inapt, inaccurate, and unscientific. It is an increasingly more important duty for all who provide technical assistance to inform their colleagues of the true value of the information they supply.

*Medical Teaching*—Although it is desirable and most stimulating that some teachers should be pursuing active research it is a tragedy that their students fail to realize that many investigations used for research purposes are frequently unnecessary or unsuitable for routine use. Sir Thomas Lewis used to teach that, although the electrocardiogram had been needed to make clear the nature of disorders of cardiac rhythm, these disorders, once they were fully understood, should be recognized by clinical methods alone. Because a number of complex renal function tests are used during research into the nature of renal disease there is no reason to use them to make a diagnosis of chronic nephritis—a diagnosis that can be made perfectly adequately by clinical methods with the aid of only the simplest urine analysis.

A detailed chemical study of fat in the stools, as used during investigations on a group of patients suffering from sprue may not be essential as a diagnostic test or as a preliminary to efficient treatment of this disease. Yet misconceptions of this type lead many conscientious men to impose upon ill patients the tedious burden of investigations the results of which cannot alter treatment or prognosis and are as valueless to science as to the patients. Competent scientific workers do not make haphazard investigations; they know that more is to be gained by thorough investigation of selected cases. For science is not merely the recording of random observations; observations must be combined with generalizations, hypotheses, and other intellectual instruments that can transform information into knowledge before scientific advance can be made.

It is increasingly difficult in these days of specialization for men to see their work with wide perspective. A critical attitude

### PORT OF LONDON AMBULANCE LAUNCH

A new timber-built ambulance launch, named the *Alfred Roach* after the former town clerk of the City of London was put into service on the Thames by the Port of London Health Authority on Sept 28. The launch, which has been built by John I. Thornycroft and Co., Ltd., is intended for the reception and transport of cases of infectious disease to the isolation hospital at Denton, Gravesend, it will also be used for the medical officer of health's general inspection work in the lower reaches of the river, from Erith eastwards for some thirty miles. It is 53 ft long with a 13 ft beam, and for normal service has a speed of 13½ knots or of 14½ knots at full power. The machinery installation comprises two six-cylinder diesel engines, and an important development is the remote control of the machinery from the helmsman's position. To handle stretcher cases a specially designed mast with derrick boom is fitted on the roof of the sick bay. Stretchers are lowered into the sick bay on to a table so fitted that the stretchers may be easily moved on runners to the settee on each side of the compartment. There is also room for eight sitting patients. The hull has well rounded quarters to minimize the risk of damage when getting away from steamers, and measures have been taken in the engine room to reduce noise and vibration to a minimum. The crew consists of a navigator, deck hand, and deck-boy, who are accommodated forward in a well furnished messroom. The launch will carry an illuminated sign for recognition in hours of darkness. When not engaged on the lower river it will lie alongside the hulk *Hygeia* which is moored off Gravesend and serves as a boarding station and base for launches.

The Port of London Health Authority now has two hulks and four launches. The second hulk, a converted sailing vessel lies at an anchorage off Gravesend. The first motor launch *Howard Deighton* is a strongly constructed steel vessel stationed at Gravesend for the use of the boarding medical officer. It has a spacious ambulance room, with accommodation for four stretcher cases or eight seated patients. The motor launch *Alfred Robertson* is allocated to the Middle River inspector and has a saloon which can be used for the reception of two stretcher cases or six sitting patients. The *Frederick Whittingham* is a small vessel allocated to the Upper River inspector, with no provision for the transport of stretcher cases but with room for four sitting patients. To these is now added the *Alfred Roach* with accommodation for three stretcher cases as well as the eight walking patients. On its inspection service it will deal with foreign home, and coastwise traders, small craft, and some houseboats, and the inspector's saloon can when required, be converted easily into an ambulance room.

not encouraged by a hasty and unbalanced education in which scholarship is so lacking that students do not have time to think and never learn to express themselves concisely and clearly in their own language. I maintain that on all sides we see evidence of a sad lack of 'scep sis scientifica,' and until this is corrected clinical medicine will remain in uncritical subservience to analyses, tests, laboratories, and specialists. Rational methods of investigation are being allowed to deteriorate to mystical rituals which are applied empirically. Dr Hendry and Dr Roberts are to be congratulated on drawing our attention to these dangerous tendencies—I am, etc.,

Cardiff

O L WADE

### Age and Retirement

SIR—There must be many, now no longer as young in years as they feel, who read with great, if perhaps wistful, interest the inspiring advice recently given by Sir Ernest Rock Carling to the British Association that age alone should not be a reason for giving up work.

It has always been possible, at least until last July, for doctors in general practice to carry out this maxim, often to the untold benefit of the community. But what of those who feel that the most important part of their work has centred round their hospitals? The imposition of an age limit makes it impossible for them to continue working there, and without hospital beds their practice must inevitably dwindle even more quickly under this new regime than heretofore.

Far be it from me to suggest it should be otherwise. They too have watched their seniors depart, with a regret perhaps not invariably so profoundly felt as they sought to imply, and now it is right that when their time comes they also should go and make way for their juniors. Must this, however, inevitably continue to mean that when they reach the age of 60 or 65 they are cut off from all hospital work? They cannot all be 'committee men' and some have little taste for this. We hear of the serious shortage of doctors of all kinds, presumably including hospital specialists. Would it be beyond the dreams of possibility that a general hospital could be founded whose visiting staff consisted entirely of consultants retired from their own hospitals? I believe such a hospital would prove so successful that it would not long remain an isolated experiment. The patients would be in the hands of those who rated the love of their work higher than the luxury of retirement, while as for the consultants one could almost visualize a Utopia free from the misunderstandings or rivalries which could have caused discord in their younger days, and with an atmosphere at last sufficiently unhurried to allow each to share in and profit by the others work.

I do not forget that the gift to see ourselves as others see us' is notoriously withheld from those of advancing years. But I think they could be trusted to intimate to each other, if necessary, when they were getting past their work.

As things are, is it surprising if those who await the inexorable approach of their retirement are sometimes assailed by the temptation to rest now on their laurels, since the time left is so short to explore further fields of knowledge or research? And yet it cannot be just vanity that compels them to believe the evidence of their senses that their results are still as good as ever they were, and that they can yet stand up to a long day's work better than some of their junior colleagues. Is there really no use, Sir, for what they still have to offer?—I am, etc.,

London NW 1

MARGARET M BASDEN

### Out-patient Electric Convulsion Treatment

SIR,—May I express the pleasure which I took in Sir W P Mallinson's article (Oct 2, p 641), a pleasure which was certainly shared by all those who during the long lasting controversy defended the use of ECT (about 1½ years ago). I feel that their point of view has been finally vindicated in the best possible way.

During my years of experience with ECT I have been able, due to careful selection, to raise the ratio of social recovery to about 85%, and using a quite familiar technique as described in the above mentioned article, complications have been practically nil in all my cases. I strongly concur especially in the use of oxygen, as according to my observations the excitements after the fit are mainly due to air hunger. I also administer a half-

pint of glucose solution as soon as the patient awakes. This combined administration of O<sub>2</sub> and CH I believe benefits the patient and cuts down the number of necessary shocks.

Regarding the out patient ECT, I should like to point out that a well frequented out patient department in a city or bigger town meets with no difficulties, but the conditions are quite different in the country. Here very often the only mental hospital is also the only place for the whole county where ECT is given. Apart from a few, the overwhelming majority of the would be out patients are debarred from the benefits of this treatment by lack of transportation. These difficulties, I think, could be overcome by a mobile ECT unit. For this purpose a car, a machine, and a doctor and a nurse would be sufficient. An electric current can be found—I hope—almost everywhere. Two or three attendants could be easily trained and supplied by the local cottage hospital or from the Red Cross and St John personnel.

Touring the country at specified places and days, ECT could be given to patients who otherwise would need hospitalization or to patients who require a maintenance dose and therefore must stay longer at the hospital. If one considers the costs of those two categories of patients alone, the mobile ECT unit would, I think, pay for itself and at the same time relieve the increasing demand for hospital beds—I am, etc.,

Bodmin

ERNEST E FELDMESSER

### Traumatic Amputation

SIR—I have just read Dr J D C Millar's medical memorandum (Sept 18, p 559) in which he states that he cannot

find a record in the literature of instantaneous traumatic amputation of the forequarter. May I quote Cheselden's *The Anatomy of the Human Body* (7th edition, p 321) which was published in 1756? Here Cheselden describes such a case, which is illustrated by a delightful engraving by Vander gucht showing the patient and the amputated arm together with the mill in which the accident happened. The miller, Samuel Wood, had his right arm torn off in 1737 while working in the mill. Cheselden notes that there was very little bleeding because

the arteries were stretched. The patient had no severe symptoms and was cured by superficial dressings only—I am, etc.

Newcastle-upon Tyne

J DUOFIELD ROSE

\*\* Readers will no doubt be interested to see the Vander gucht engraving mentioned in Dr Rose's letter, and we have therefore reproduced it here. Dr R G Bartelot, of Trowbridge, has also drawn our attention to Cheselden's account of the accident—ED BMJ

### Ruptured Uterus

SIR—Mr Keith Vartan (Sept 25, p 602) has done a service by describing his case of intrapartum uterine rupture following classical caesarean section in a previous pregnancy. Unfortunately the real lessons which are to be learnt have not been emphasized. He writes that a classical caesarean was performed—but does not say by whom—on a primigravida of 26 on account of a breech presentation, with extended legs. Unless there was some other condition present this can only be judged as bad obstetrics. It reads as if she could quite well have been delivered vaginally, but if caesarean section was necessary, why not it

lower-segment approach? The classical operation, except in some rare cases where the foetus cannot be extracted through the lower segment because it has not formed, is an abomination, and it is time those who frequently practise it correct their ways. Even without any previous operation the upper segment of the full-time pregnant uterus may have thin areas in it, so it can hardly be surprising that once it has been cut it occasionally ruptures. I have seen two cases of rupture of a classical scar in the last year.

The second lesson is that an afebrile convalescence after a classical caesarean section is no guarantee of the integrity of the scar. This depends just as much on the extent to which the puerperal contractions of the uterus have loosened the sutures and so upset the close approximation of the cut surfaces. The advantages of the lower segment incision are that the wound is at rest during healing, that the scar is covered by peritoneum, that abdominal adhesions are reduced to a minimum, and that subsequent spontaneous rupture of the scar—particularly if the incision has been placed as low as possible—practically never occurs—I am, etc.,

Manchester

C SCOTT RUSSELL

### Treatment of Burns

SIR—The successful treatment of two persistent cases of second-degree burns with a 1% solution of silver dinaphthylmethylethane disulphonate is reported.

**Case 1**—An epileptic and mentally defective female aged 36 was admitted to hospital on March 10, 1948, with first and second-degree burns of a large area of the back following a fall into the fire during a fit. She was treated until March 20 with tulle gras and local and systemic sulphonamides and penicillin, and then sedatives only, as she refused further local treatment. When seen by me on April 20 she was complaining of great pain and showed a large area of necrosis and sloughing on the right side of the back. She was treated with daily wet dressings of 1% silver dinaphthylmethylethane disulphonate solution. By April 27 the burn was granulating well. On May 11 a 1% ointment of the same compound was applied twice daily, and by June 29 the burn was completely healed with a freely movable scar.

**Case 2**—In March, 1946, a soldier sustained a second degree burn of the right thigh and leg, due to the explosion of a phosphorus bomb which he was carrying in his trousers pocket. Four attempts at skin grafting during the next two years were only partially successful. When seen by me on March 16, 1948, he showed large unhealed infective areas of the right thigh and multiple pustules above and below the knee. Bacteriological examination showed *Staphylococcus aureus* and *albus*, *Bacillus proteus*, and diphtheroids. The upper part received twice daily dressings of 1% silver dinaphthylmethylethane disulphonate solution and the lower part 1% of the same compound in "eucerin" ointment. After seven days the upper part was dry and the lower part showed no lesions at all. The ointment was then applied to the whole leg and he was allowed up. Bacteriological examination on March 26 showed no growth after 48 hours. On April 20 he was discharged from hospital with three small granulating areas, having been in bed for over two years.

—I am, etc.,

London W 1

MICHAEL J FENTON

### Treatment of Varicose Ulcer

SIR—It would appear to be a common misapprehension that the treatment of varicose ulceration lies in ligation and sclerosis of the concomitant varicose veins. Dr John Borrie (Sept 5, p 618) indicates that lumbar sympathectomy was not resorted to until adequate high ligation, multiple division of tributaries and excision of veins had been performed without any healing of the ulcer, and again, "ulcers of considerable size" whose possessors refused to have their veins treated (Dr Eric Puddy, Sept 25, p 619).

At the Metropolitan Hospital we have seen, and propose in the future to produce figures in support of the contention that ligation and sclerosis of veins will not alone produce healing of a chronic varicose ulcer. The only certain way of healing a chronic varicose ulcer is to use the elastic-compression bandage technique. Ligation and sclerosis of veins are performed either during treatment or after the ulcer has healed, and the patient is supplied with elastic stockings which she must wear for the rest of her life but these measures are purely incidental to the healing of the ulcer and are carried out to prevent a recurrence in the future.

One other most important point lies in ensuring that the patients receive the permanent personal attention of an enthusiastic member of the medical staff. So often the varicose-ulcer clinic is the *bête noire* of the most junior member of the 'house,' who, remembering the "Unna's clinic" of his student days, rushes in at weekly intervals holding his nose, inscribes the magic 'Rep,' and disappears even more quickly than he materialized. It should be remembered that a well-run varicose-ulcer clinic has no odour—I am, etc.,

London N 10

S M RIVLIN

### Self-administered Pneumothorax Refills

SIR—The remarkable knowledge of their disease possessed by certain patients suffering from pulmonary tuberculosis as a result of prolonged institutional treatment is an accepted fact. Most workers in this field will also have witnessed the courage and resourcefulness of such patients in an emergency. The courage required to devise an apparatus for and to self-administer pneumothorax therapy must, however, be unique and for that reason worth recording in your columns even though the venture was misguided and fraught with danger. I myself was so curious about the procedure that I persuaded my patient to describe it in his own words, the relevant part of which I reproduce here. I should be greatly interested to learn of any comparable experience.

A seaman aged 25 was found following repeated haemoptyses, to have pulmonary tuberculosis, with a positive sputum. He had tuberculous lung infiltration and cavitation involving the upper zone of the left lung and a left artificial pneumothorax was induced which was contraindicated owing to adhesions. Following thoracoscopy and pneumonolysis a fairly selective collapse was obtained although there was some fluid at the base. Regular refills were maintained for two years after which the patient moved from one area to another where the facilities for getting refills were unsatisfactory and he discontinued them. Soon afterwards the upper zone of the right lung became affected and he took action as follows.

"I had a few yards of medical rubber tubing on hand, and a knowledge of the Lillingston-Pearson apparatus and how to use it. I did not see why I could not construct one within a few days and so I obtained some glass tubing of 3/10 in diameter from a chemist and bent a length of it over a gas ring and formed a U-tube. I then got two Horlicks bottles cleaned out and marked them off into divisions by using a file. Each division represented 100 ml. In order to get the bottles marked out as accurately as possible I used a 20 ml syringe and repeatedly filled it with water and emptied it into a bottle. You will quickly see that I needed only to fill the syringe five times and empty the water it contained into one of the bottles in order to make up each 100 ml. As soon as I made up each 100 ml of water I marked it off on the outside of the bottle. When I completed one bottle which, incidentally, held 550 ml, I went through the same procedure with an identical bottle. I completed the apparatus by making two corks from a couple of heavy rubber torches and bending some more glass tubing to form two siphons also a further two tubes for air to run through. Afterwards I made two air filters.

"I did not use the apparatus immediately, as I wanted to see if the straining would stop of its own accord, but one morning I woke up with a terrible headache and a general feeling of there being something wrong. A few minutes after that I began to cough up thick bright red blood which not only came from my mouth in great quantity but also poured through my nose. My doctor was called and he prescribed linnet codeine and gave me an injection of ½ gr (32 mg) of morphine. After having a further eight or nine haemoptyses during the following week, I decided to collapse my left lung completely and without my doctor's knowledge.

"Perhaps you will wonder how it was that I did not puncture my lung with the needle, which was not an induction needle but just an ordinary refill one, but the explanation is simple—I knew that I had a fair amount of fluid surrounding the lung in question and that consequently it would be partly collapsed.

"I got my apparatus ready one morning, carefully boiled the needle, a piece of rubber tubing and a glass joint, and after thoroughly washing my hands, I cleaned a place on the side of my left chest. I then pushed the needle between two ribs which were not much above where I estimated the fluid level to be, as I was anxious to select a place for the needle where, maybe the greatest degree of collapse should be present. My brother stood by to attend to the clips on the rubber tubes.

"The needle passed through the outer pleural surface quite easily and with very little discomfort. I pushed the needle in until my breathing produced a regular swing on the manometer, and then after my brother had closed the tube which led to it with a clip I let it

to let the air in slowly, which he did. I let 150 ml of air pass into the pleural space, then had the siphon stopped with the other clip, and before I removed the needle I took a final pressure reading. I took no intermediate readings. The initial pressure was -16-1 and the final pressure -10-1. I repeated the refill next day, when the initial pressure was -10-1 and the final pressure -4-1.

"After the first refills I gave myself air once a week for three months and then once a fortnight for three months. By the time I was admitted to hospital, in June, 1947, I was giving myself three weekly refills of 250 ml of air. My fluid had dispersed by that time, but for several weeks I had been getting some queer pressure readings after the induction of air—some were very high positive pressures—and I came to the conclusion that perhaps I had a spontaneous pneumothorax, but of course I could not prove it to myself."

He came under my care early this year—3½ years after the induction of his left-sided pneumothorax. He was afebrile, with a pulse rate of 100, and very breathless on exertion, he had a chronic cough with an ounce of mucopurulent sputum which on repeated examination by routine and concentrated methods was negative for tubercle bacilli.

Clinical and x-ray examination of his chest showed a healed fibroid lesion of his right lung, complete collapse of his left lung complicated by a broncho-pleural fistula, and his lung has remained so well collapsed that he has required no further refills. His left intrapleural pressures have remained constant at about -10. The complication of his broncho-pleural fistula cannot be dissociated from his self-administered pneumothorax refills—I am, etc.,

London W1

PHILIP ELLMAN

### Double Stethoscope

SIR—Some time ago an account of a double stethoscope appeared in the *British Medical Journal* (1935, 1, 1033). It

may interest you to know that about thirty-five years ago I had a stethoscope of that type made for me by Messrs Graham and Curry, Great Victoria Street, Belfast. I enclose a photograph of the original taken by Mr Birrell, the radiographer to the tuberculosis department. The late Dr Trimble was very much interested and had a beautiful model made which Dr Summers obtained on the death of Dr Trimble. Some of the old physicians of that period with their single stethoscope changed quickly from side to side to listen to the breathing in the same phase. The double end was made not to

listen to two places at once except perhaps in the case of a cardiac murmur. However, in chest work, except for a dry pleurisy the radiograph has entirely replaced auscultation in the diagnosis of early tuberculosis—I am, etc.,

Belfast.

JAMES SHAW

### Foreign Body in the Ear

SIR—The following case is reported on account of its rarity.

A young woman attended surgery complaining of severe pain in the left ear. She stated that she was passing close to a hedge when she suddenly felt something brush against her cheek and immediately afterwards experienced acute pain in the ear. I saw her less than half an hour later.

She was slightly shocked, as evidenced by pallor and pulse rate of 120. Examination of the drum was exceedingly difficult owing to exquisite tenderness but the drum was inspected and appeared to be normal. The only abnormality observed was what appeared to be a hair in the external auditory meatus. This was removed with no difficulty, and she experienced immediate relief of all pain.

Careful examination of the drum was possible, and a small bleeding point on the lower anterior quadrant showed where the foreign body had perforated it.

The foreign body was a small grass seed consisting of three seeds fused together at one end, ending as a sharp point.

Foreign bodies perforating the membrana tympani are uncommon and a grass seed accidentally brushed against it must be exceedingly rare. The wound healed uneventfully.

In the writer's opinion the points of interest were the apparently normal appearance of the drum and the case with which the grass seed could have been overlooked as the cause of the pain—I am, etc.

Westcliff-on-Sea Essex

A RYDER LEWIS

### The Walking-calliper

SIR—Among the annotations in your issue of Sept 18 was one on improvements in artificial limbs (p 565). It is obvious that a considerable amount of time and thought is given to the subject both by research workers and patients. It is this co-operation between patient and research worker which must be the most important factor in the improvements made in the appliances to be worn.

I want in this letter to raise the question of another type of patient, wearing an appliance of a different kind. I refer to the patient with the 'walking calliper' or 'walking instrument'. As far as I know there is no organization concerned with research in this particular instrument. Perhaps this is because the wearers are fewer, and some are temporary only. Since the recent epidemic of acute anterior poliomyelitis in this country there must be many more permanent wearers.

I think that everyone will agree that, compared with an artificial leg the walking calliper presents itself as a cumbersome contraption to which the term 'Heath Robinson' could also be applied. I feel sure that a research organization in collaboration with patients, as in the case of artificial limbs, could produce a greatly improved instrument and one which would not lay itself open to the remark from a child not more than usually observant, 'What are those things on your shoes?'—I am, etc.,

Norwich

H L ROGERSON

### Shortage of Nurses

SIR,—In a different context the *Statist* said 'If a man smitten by infantile paralysis were told by his doctor that one of his limbs showed some slight sign of restored activity, he might well feel relief, but he would hardly stand up and cheer. If a householder were told by a fireman that the house was still blazing merrily but that an outburst of flame in the back attic had been subdued, he might well be grateful, but he would hardly astonish the onlooking neighbours by flinging his hat in the air and publicly congratulating himself on his energy and perspicacity. If the crew of a wrecked ship adrift in an open boat were told that those bailing out the flooding waters had managed to scoop back into the ocean a few pints more than in the previous hour, they might well be grateful to Providence, but they would hardly set up a psalm of praise to the bailers.'

Mr L H Hornsby's defence (Sept 25, p 622), therefore will scarcely make us hysterically overjoyed, especially when we find that one district of a town has but one district nurse for 15,000, and that a large general hospital through shortage of nurses has closed at least one ward, which is now occupied by the finance officer and his staff. The truth is that despite the overall increases in numbers the gaps in the ranks are not closing. Local authorities among others have appetites which increase with eating—I am, etc.,

Heanor Derbyshire

PHILIP TURTON

### POINTS FROM LETTERS

#### Spraying Fruit

Mr MAX C L BEALE (Sissinghurst, Kent) writes: Being a fruit grower I was interested to read Dr James Forrest's letter (Sept 18, p 577). Whether he should attribute his discomfort to spray chemicals is a moot point. The following programme might have been carried out, but it should be remembered that spraying is an expensive business and is seldom done unless really necessary. Strawberries: Lime sulphur (3% solution) in March to control tarsonemus mite; sulphur dust (about 40 lb per acre) in May and July to control mildew; nicotine vapour (if required) to control aphids, if root-eating grubs present a poison bait of bran and Paris green (copper arsenite) might be put down; a grower might use a growth promoter spray such as alpha-naphthalene acetic acid during blossom period to encourage a set of fruit. Red currants: A tar oil (5%) or petrol-DNC (6%) spray during dormant period; lime sulphur (2% solution) about April to control big bud mite; if aphids serious a dormant nicotine spray might be applied. Raspberries: Derris or DDT applied ten days after first flower opens to control raspberry beetle. If applied in dust form the DDT would be a 5% dust put on at the rate of 40 lb (approx) per acre. Concentration of summer sprays: DDT, if applied as a wet spray, 4 lb (35% DDT) to 100 gal of water, nicotine, 8 oz (95-98%) to 100 gallons of water and of oil

CHRONIC skin diseases such as acne seborrhæica, oleosa and rosacea are very distressing to the patient. In the case of women it is particularly difficult to treat facial lesions without further disfigurement.

Genatosan Products offer two happy solutions to the problem. Dermatological Cream No. 10 (Zinc Sulph 3%, Potass Sulphuric 3%) contains the active in-

gredients in a non greasy base. For day use the cream may be employed as a powder base without detracting from its therapeutic value and your patients will appreciate the lack of restriction on the use of cosmetics.

Alternatively or additionally Fissan Ichthammol Powder (2% Ichthammol) is flesh tinted and can be used as a face powder.

## Antacid and Adsorbent

The particular value of MAGSORBENT in chronic hyperchlorhydric disorders depends upon the moderation of its rate of interaction with acids. The time required for complete interaction approximates to the normal emptying time of the stomach. It can, therefore, be taken in generous excess of the amount required to combine with the acid present in the stomach at any particular moment without risk of overneutralisation.

Formula: Magnesium Trisilicate 100%.

Samples of MAGSORBENT Powder and Tablets, also literature, are available on request.

Twelve drops daily for the baby, 10 to 15 drops for the adolescent and up to 20 drops for the debilitated adult. Indeed, having the indication for additional vitamins A and D, Adecolin Liquid can be prescribed at the precise dosage to meet the patient's needs. Convalescence, malnutrition and proneness to infection of almost any kind are absolute indications for Adecolin. But when there is cause to believe that the dietary yield of vitamins A and D is near the borderline of insufficiency, there is a particular place for Adecolin among routine measures of prophylaxis. Adecolin Liquid is almost tasteless for administration to infants it may be mixed with the bottle feeds or with the usual fruit juice.

### "What is Benger's Food?"

"You have heard the medical evidence and you may have formed the conclusion that in spite of his undoubtedly high qualifications, Dr Telmy-More was not entirely clear in his own mind as to the nature and functions of Benger's Food

'The fact that his father prescribed it and his grandfather before that, whilst indicating continuity in the treatment of gastro-intestinal disorders, is not in itself conclusive evidence that the witness was fully aware of their reasons for so doing

And, whereas at one point in his testimony he admitted the unique enzymic action of Benger's Food in modifying milk, at another he appeared to confuse Benger's Food with ordinary bed-time drinks in which this principle is absent

'Nevertheless Dr Telmy-More's frank admission that a busy practitioner is not always able to keep au fait with a wide variety of proprietary products impressed me, as did his declared intention of questioning the medical representative of the makers of Benger's Food at the first opportunity "

## Allaying Anxiety

For economic and medical reasons, the doctor's advice is being increasingly sought on the subject of "PLANNED PARENTHOOD" and Birth Control, in its clinical aspect, is rapidly becoming a new branch of Medical Science

## GYNOMIN

THE SCIENTIFICALLY BALANCED ANTISEPTIC AND DEODORANT CONTRACEPTIVE TABLET

GYNOMIN is included in the approved list of contraceptives issued by the Family Planning Association. Closely approaches the ideal and adequately fulfils physical and psychological requirements.

- 1 Spermicidally efficient and clean in application.
- 2 Non-irritant, non greasy and harmless to health
- 3 Keeps perfectly in all climates

FORMULA Each tablet contains Sodium Bicarb B.P. 0.14 gm.  
Acid Tart B.P. 0.122 gm. Sod.-dichloro-p-sulphamide benz-  
zoate, 0.0128 gm. Perfume q.s. Excipient to 1.16 gm.

ready spray about 250 to 300 gallons would be used over an acre. There is a possible explanation. Was the fruit grown by an amateur? If so, he may have doubled the recommended concentrations (an easy thing to do if making up small quantities) in order to ensure a "kill". It would seem he nearly succeeded.

#### Whooping-cough and Measles

Dr S N DHANANJAY (Harnhar, India) writes. With reference to Dr B L Hodge's letter about whooping cough and measles (Aug 7, p 312), I wish to bring to your notice a similar case treated by me. A boy of 8 years was brought to me on Sept 6 with a history of cough since fifteen days and slight temperature since that morning. He was found to be suffering from whooping-cough, and as he had slight temperature I postponed administration of anti pertussis vaccine. Next day the boy developed fever and coryza, and on Sept 9 typical rashes of measles developed. The boy was kept on plain diaphoretic mixture and one tablet sulphathiazole t.d.s. till the signs disappeared on Sept 13. To my surprise he had recovered from the distressing cough and the lungs were also clear. I was also wondering why an attack of measles should cure whooping cough.

#### Third Attack of Mumps

Dr W H SCOTT EASTON (Frinton on Sea, Essex) writes. Dr W W Newton reports (Sept 18, p 577) the case of a young woman with a fourth attack of mumps. I have just visited a boy of 11 who is suffering from his third attack of true mumps since April, 1948. He has now infected his brother.

#### Hippocratic Oath

Dr F J FISH (Whitburn, Co. Durham) writes. I was surprised to read in the leading article on "World Medical Association" (Sept 25, p 605) that the Hippocratic Oath is rarely found in histories of medicine. An English translation of the Hippocratic Oath is to be found in the following histories of medicine: Castiglione, A., *History of Medicine* (New York, 1941, trans. E B Krumbhaar), Guthrie, D., *History of Medicine* (London, 1945), Stubbs, S G B., and Bligh, E W., *Sixty Centuries of Health and Physick* (London, 1931). While none of these books can rival Garrison, F H., *History of Medicine* (Philadelphia, 1929), they are standard works and can be purchased or borrowed more easily than Garrison's book.

#### Caesarean Section in Breech Delivery

Dr K D SALZMANN (Reading) writes. I was interested to read of Mr Keith Vartan's case of spontaneous rupture of the uterus following previous caesarean section (Sept 25, p 602). If that operation was performed only for the reason given—extended breech presentation—his comment on the case is sadly lacking. Here was a primipara of 26 who underwent a caesarean section. As a consequence this young lady lost her uterus, lost her second child, lost all chance of having any more children, and nearly lost her life. If that is not the most damning indictment of those who resort to surgery instead of practising obstetrics I would like to know what is.

#### Liquor Picis Carbonis (B.P.)

Dr J KELVIN (Glasgow) writes. Dr I Berenblum (Sept 25, p 601) finds that 7 out of 12 mice painted with the medicament developed papillomata at intervals varying from ten to forty weeks. He states that "this raises the important question whether its clinical use is not without danger to the patient." Perhaps a pinch of salt put on the tails of the mice might produce similar irritant changes. Dr Berenblum does not say how long it would take the mice to develop lesions after the application of 1% or 2% preparations (in excellent ointment bases) as used harmlessly in protracted medical practice. The answer is probably never.

#### Empirical Methods

Dr R P BEATTY (Swindon) writes. Dr A R McClure's letter (Oct 2, p 662) is a reminder of the tendency to overlook the experiences of the past and to ignore possible remedies until their mode of action is explained. Fifty years ago I was told, with disgust and scorn, of an old "wise woman" in Co. Neath who made a salve from a black mould in which the peasants had great faith. Probably this was one of the penicillium groups. No doubt there are other traditional drugs or herbs whose action would repay investigation.

#### Post anaesthetic Vomiting

Dr F R RUSSELL (London, NW2) writes. During the past two years I have studied the causes of post operative vomiting due to anaesthesia and I found that on questioning those patients in whom vomiting did occur the story given was nearly always the same—namely, that on recovering consciousness they complained of thirst, and that vomiting occurred immediately after quenching this thirst with water, orange juice, or tea. I am therefore convinced that prophylactically, the patient must be warned before anaesthesia is induced that only minute sips of water should be taken on recovering consciousness if they complain of thirst.

## Obituary

Dr HAROLD EDWARD GIBSON who died suddenly on Sept 16 at the age of 67, had been in practice for many years at South Godstone, Surrey. His father was in the I.C.S., and he was born in Madras. Dr Gibson studied medicine at Queen's College, Oxford, and King's College Hospital, and graduated in 1908, proceeding M.D. in 1918. He served in the R.A.M.C. during the 1914-18 war. Dr Gibson held many appointments in the Godstone district. He was medical officer in charge of the electrotherapy department at Edenbridge Hospital, medical officer to St Barnabas Homes for Aged Clergy, medical officer for South Godstone District, and he also looked after the Boys' Farm School at Blindley Heath. He retired from active practice a year ago and had just settled at Seaton, in Devonshire, a few weeks before his death. Dr Gibson was an active member of the Reigate Division of the British Medical Association, and was president of the Division from 1942 to 1944. He is survived by his widow and son, to whom the sympathy of his colleagues will be extended.

Dr WILLIAM OWEN-PRICHARD who died on Sept 21, was born in Anglesey on Oct 21, 1875. After leaving Edinburgh where he qualified, he served in the South African War and then entered the Colonial Medical Service. He held appointments in Somaliland, Uganda, and Kenya, at first attached to the King's African Rifles and then as a civil medical officer. He filled the posts of senior medical officer and acting principal medical officer and was in charge of the European Hospital at Mombasa at one time. During the 1914-18 war he served in German East Africa, and then returned to Dar-es-Salaam as S.M.O. of the European Hospital. He retired from the Colonial Medical Service in 1923, and subsequently served with the R.A.M.C. in Aldershot and Bordon as a temporary medical officer. In 1943 he became medical superintendent of the Old Windsor Hospital. He leaves a widow and one son and daughter.

Mr JAMES ELLIOT SQUARE died on Sept 23 as he approached his ninetieth birthday. He was the oldest and perhaps the most highly esteemed member of the medical profession in Plymouth. Born on Oct 1, 1858, he studied medicine at St Bartholomew's Hospital where he became house-surgeon and at the London Ophthalmic Hospital, where he was clinical assistant. Qualifying in 1881, he took the F.R.C.S. in 1883. Throughout his long professional life he practised in Plymouth his native city and for thirty-seven years he was honorary surgeon to the Royal Eye Infirmary. He took a special interest and pride in the Plymouth Medical Society, the seventh oldest in the United Kingdom, and recently he produced a short history of the Society's transactions dating from its origin in 1794. He was honorary treasurer for sixty years—a record tenure of office for the Plymouth Society and believed to be a record for any similar society in this country. Last year his colleagues gave a luncheon in his honour and presented him with his portrait in oils in recognition of his long and devoted services to the Society. Considering his age, Mr Square remained physically and mentally alert, and his final illness was only a matter of hours. Elliot Square was a grand gentleman, ever courteous and kind. Tribute was paid to his memory and good deeds at a service in St Matthias Church where he had been a lifelong worshipper. His wife died many years ago. He leaves a son and three daughters, to whom his colleagues offer sincere sympathy in their loss of a revered parent.—G.D.

Dr CHARLES EDWARD LACEY died on Oct 3 at the National Hospital, Queen Square, after a brief illness. Dr Lacey, who was only 29, graduated M.B. Ch.B. at Leeds in 1942. He served in the R.A.M.C. until September, 1945, when he had to relinquish his commission owing to ill-health. At the time of his death he was registrar to the department of psychological medicine at the National Hospital, Queen Square, and had already won the high regard of all his colleagues.

E.S. writes. Lacey's premature and tragic death robs psychological medicine of a young man who might have gone very far. He was gifted beyond the common, highly intelligent and alert to new ideas. He was interested in every aspect of psychiatry, but particularly in those most closely related to general medicine and neurology. He had a natural clinical gift and applied it in careful and detailed study of his patients. He was an enthusiastic reader and had a grasp and comprehension of surprising maturity. All the requirements were there for a career of brilliance had not fate intervened. His warm uncomplicated, and modest personality made him many friends at the National Hospital who will regret him personally as much as the cutting short of a life of such promise.

## Universities and Colleges

### UNIVERSITY OF LONDON

Robert Cruickshank M D F R C P, D P H, has accepted an invitation to take the Chair of Bacteriology tenable at St Mary's Hospital Medical School from Jan 1, 1949

A series of lunch hour lectures on a variety of subjects has begun in the Anatomy Theatre of University College (entrance from Gower Street, WC) and will be continued on Tuesdays and Thursdays, from 1.15 to 2 p.m. until Dec 7. The series includes lectures by Dr D B Fry Ph D on Visible Speech, on Oct 26, by Professor J Z Young, F R S, on Process of Learning in Octopus, on Nov 2 by Dr S J F Philpott, D Sc, on "Psychology as a Science" on Nov 16 and 18 and by Dr J T Autken on 'Posture,' on Nov 25. Admission to the lectures is free, without ticket. Full particulars may be obtained from the secretary of University College, Gower Street, London WC1.

The first of a course of four public lectures entitled "The Electron Microscope and its Biological Applications" was given on Oct 11 by Dr E M Crook, M Sc, Ph D, in the Department of Biochemistry University College, Gower Street, WC. The remaining three lectures will be delivered by Dr Crook on Mondays, Oct 18 and 25 and Nov 8 at 4.45 p.m. at the same place. Admission is free, without ticket.

A special University lecture in human anatomy and morphology will be delivered in French by Professor G Levi, of the Istituto di Anatomia Umana, University of Turin, at University College (Anatomy Theatre) Gower Street WC, on Friday Nov 5, at 5 p.m. Professor Levi will speak on Relations of Interdependency between Various Parts of the Nervous System in the Embryo and in the Adult. The lecture is addressed to students of the University and to others interested in the subject. Admission is free, without ticket.

## The Services

Surgeon Captain W J Colborne, R N, has been appointed an Honorary Surgeon to the King in succession to Surgeon Rear Admiral J A O Flynn, C B, R N, retired.

### DEATHS IN THE SERVICES

#### MAJOR GENERAL R S HANNAY, C B, C M G, D S O

Major General R S Hannay, who was Colonel Commandant of the R A M C from 1939 to 1941, died on Oct 5 at his home in London at the age of 77.

Robert Strickland Hannay Fuhr began his medical studies at Queen's College, Belfast, where he took the triple Scottish qualification in 1893. He joined the Army Medical School at Netley in 1898. During the South African War he was at first with a battalion and was present at a number of the major actions, but when General Roberts reached Pretoria he was transferred to the staff. He received the Queen's Medal with six clasps. When the B E F embarked for France in 1914 Fuhr was detailed for duty with a medical unit but was again transferred to the staff, finally serving as medical director of the 1st Division, which after the war formed part of the Army of the Rhine with headquarters at Bonn. Fuhr was mentioned in dispatches five times and made a C M G, and he was also promoted brevet colonel. At this time he changed his name by deed poll to Robert Strickland Hannay. His next appointment was as D D M S in Turkey, and on his return home he was created C B and promoted to the rank of major general in 1926. Hannay then took over as D D M S Southern Command and in the same year was appointed honorary surgeon to the King. Major-General Hannay retired in 1930. In the following year he became a Member of Council of the British Medical Association and served for three years on the Council and on the Naval and Military Committee.

Under a short term bursary scheme run by the British Council about 120 industrial and professional workers from overseas are visiting Britain this year for three to six months. These include a French radiotherapist, Dr Bertoluzzi, who is spending six months at the London Hospital; a midwife from Iceland, Miss M Gudmunds dottir who is dividing her four months' bursary between Edinburgh Infirmary, Perivale Maternity Hospital, Queen Charlotte's Hospital and the City of London Maternity Hospital; a Lebanese, Mr A M Talhouk who is studying pest control with Pest Control Limited Cambridge; and Miss J E Munz an Australian who is studying nursing administration at the Royal College of Nursing for three months.

## INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Sept 25

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year for (a) England and Wales (London included) (b) London (administrative county) (c) Scotland (d) Eire (e) Northern Ireland. Figures of Births and Deaths and of Deaths recorded under each infectious disease for (a) The 126 great towns in England and Wales (including London) (b) London (administrative county) (c) The 16 principal towns in Scotland (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases. A blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)

Deaths (0-1 year) Infant mortality rate (per 1,000 live births)	250	30	53	13	12	369	31	67	32	15
Deaths (excluding still births) Annual death rate (per 1 000 persons living)	4 008	651	556	149	106	3 665	569	482	179	102
Live births Annual rate per 1 000 persons living	7 458	1166	885	463	223	8 659	1349	1076	361	247
Stillbirths Rate per 1 000 total births (including stillborn)	169	17	23	—	—	222	30	26	—	—

\* Measles and whooping-cough are not notifiable in Scotland and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales (London (administrative county)) will no longer be published.

‡ Includes primary form for England and Wales (London (administrative county)) and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales (London (administrative county)) are combined.

|| Includes puerperal fever for England and Wales and Eire.

## EPIDEMIOLOGICAL NOTES

## Discussion of Table

In *England and Wales* an increase was recorded in the notifications of scarlet fever 143, measles 89, dysentery 18, and there was a decrease in the incidence of whooping-cough 376.

A small rise in the notifications of scarlet fever was reported throughout the country and no large changes in the local trends were recorded. No changes of any size were noted in the returns of diphtheria. The largest rises in the notifications of measles were Yorkshire West Riding 89, Essex 46, and Gloucestershire 45, the greatest falls were Cumberland 88 and Durham 55. The largest decreases in the incidence of whooping-cough were Lancashire 75, Yorkshire West Riding 62, Cheshire 40, and there was a small decrease in the number of notifications in the remainder of the country except in the West Midland counties, where a slight rise was reported.

A further 20 cases of typhoid fever were notified from the outbreak in Shropshire, Oswestry R.D. The rise in the notifications of dysentery was contributed by London, where the notifications rose from 5 to 22, most of this increase was due to an outbreak in Chelsea which affected 10 persons.

Notifications of acute poliomyelitis have been remarkably constant during the past six weeks and have only varied between 70 and 72. During the week the largest returns of acute poliomyelitis were Staffordshire 7 (Wolverhampton C.B. 3), Warwickshire 7 (Birmingham C.B. 6), Yorkshire West Riding 7 (Sheffield C.B. 3), Glamorganshire 7 (Cardiff C.B. 3), and Essex 5.

In *Scotland* increases in the notifications of measles 15 and dysentery 10, with a decrease for acute primary pneumonia 19 were the only changes of any size in the trends of infectious diseases. The rise in the incidence of dysentery was due to an increase in Glasgow from 29 to 38.

In *Eire* an increase of 39 was reported in the notifications of scarlet fever and a decrease of 29 in the cases of diarrhoea and enteritis. The change in the trends of both these diseases was due to the experience of Dublin C.B.

In *Northern Ireland* a decrease of 11 in the notifications of scarlet fever was the chief feature of the returns.

## Quarterly Return for Eire

The birth rate for the June quarter was 23.8 per 1,000 and was 1.4 below the June rate of 1947. The infant mortality was 46 and was the lowest rate ever recorded for any quarter. Infant mortality during the five preceding second quarters had varied between 58 and 77. Maternal mortality was 1.4 per 1,000 registered births, and was 0.1 above the rate for the second quarter of 1947. The general death rate was 12.5 per 1,000 and was 2.5 below the rate for the second quarter of the preceding year. Deaths from pulmonary tuberculosis numbered 702 and from other forms of tuberculosis 150, these totals were 110 and 100 respectively below the number of deaths in the June quarter of 1947. The principal epidemic diseases were responsible for 185 deaths, 125 fewer than in the second quarter of the preceding year. The chief causes of death under this heading were 85 from diarrhoea and enteritis, 63 from whooping cough, and 25 from measles.

## Week Ending October 2

The notifications of infectious diseases in *England and Wales* during the week included scarlet fever 1234, whooping-cough 2204, diphtheria 114, measles 3546, acute pneumonia 402, cerebrospinal fever 28, acute poliomyelitis 83, dysentery 58, paratyphoid 6, and typhoid 40.

## NEW AMBULANCES FOR LONDON

A new type of motor ambulance designed for the service of the London County Council was shown at the Motor Exhibition at Earl's Court on Oct. 7. The chassis is specially adapted for transporting recumbent patients in the most efficient manner. It is low loading, the floor being only 21 in. from the ground with three steps each 7 in. in height. By means of anti-roll bars and the careful balancing of the periodicity of the front and back springs any unpleasant jolting is avoided. The interior of the vehicle which measures 10 ft. by 6 ft. has rounded corners, a device for admitting warm air in winter and cool air in summer, and provision for an emergency exit should the door become unusable. The L.C.C. has ordered 20 of these vehicles. The present service of the Council comprises more than 300 ambulances, with an operative staff of over 500 working from 23 ambulance stations, shortly to be increased to 26.

## Medical News

## New Members of Medical Research Council

By an Order of the Committee of Privy Council for Medical Research Viscount Addison and Sir George E. Schuster have been appointed members of the Medical Research Council with the approval of the Committee of Privy Council. The Medical Research Council has appointed Viscount Addison to be chairman in succession to Lord Balfour of Burleigh, and Sir George Schuster to be treasurer in succession to Sir William M. Goodenough, Bt. By the same Order made after consultation with the Medical Research Council and with the President of the Royal Society the following have also been appointed members of the Council: Sir Frederic C. Bartlett, F.R.S., Professor of Experimental Psychology in the University of Cambridge, Sir Howard W. Florey, F.R.S., Professor of Pathology in the University of Oxford, and Professor Geoffrey Jefferson, F.R.S., Professor of Neurosurgery in the University of Manchester.

## Responsibilities in Health Service
